# APOLLO 5 MISSION (AS-204/LM-1) OPERATIONAL TRAJECTORY

## VOLUME I - MISSION DESCRIPTION

By Edwin G. Dupnick and Veit Hanssen

### 1.0 SUMMARY AND INTRODUCTION

This document revises the spacecraft operational trajectory for the unmanned Apollo 5 mission (AS-204/LM-1). The operational trajectory is intended to satisfy mission objectives within mission rules and constraints (ref. 1, 2, and 3, respectively). It defines the nominal mission profile that has been generated based on the spacecraft data presented in section 3.0 of this report and revision 1 of the launch vehicle operational trajectory (ref. 4).

The revised operational trajectory is similar to the mission profile defined in reference 5. However, this report reflects the revisions and modifications to the mission profile that have been issued since publication of reference 5. The mission profile incorporates the free-flight attitude control and powered-flight guidance-steering logic utilized in the spacecraft onboard program (ref. 6). The data presented for the ascent-to-orbit phase and the orbital coast phase from insertion to LM/S-IVB separation are based on data extracted from reference 4.

This report is presented in four volumes. Volume I summarizes the spacecraft data used in the generation of the mission profile and describes the major mission phases and events, tabular time history of salient spacecraft position, velocity, and weight characteristics, and MSFN coverage data.

Volume II of this report contains the tables of the spacecraft trajectory simulation and reference coordinate system definitions.

Volume III presents detailed tracking time histories of radar data for the land-based MSFN stations and the tracking ships that are currently planned to be available for support during this mission. In addition, AOS/LOS data is provided.

The consumables requirements for the nominal Apollo 5 mission are given in Volume IV.

MSFN Manned Space Flight Network

RCS reaction control system

SLA spacecraft-IM adapter

### 3.0 SUMMARY OF INPUT DATA

#### 3.1 Saturn IB Launch Vehicle

The Saturn IB launch vehicle which will be used to insert the S-IVB/SLA/IM combination into the initial earth orbit is comprised of the S-IB and S-IVB stages and is illustrated in figure 1. A brief launch vehicle weight statement obtained from reference 4 is presented in table I. The characteristics of the insertion state vector are presented in table II.

#### 3.2 Spacecraft (LM-1)

The Apollo spacecraft which will be inserted into orbit by the AS-204 launch vehicle consists of LM-1, a spacecraft IM adapter, and an aerodynamic shroud. The specifications for these items have been obtained from reference 6. An outboard profile of LM-1, including the spacecraft coordinate system definition and rotation convention, is presented in figure 2. The spacecraft data required to support this operational trajectory revision are presented in the following subsections.

3.2.1 Weight characteristics.- The spacecraft inert structure and propellant weight characteristics were obtained from reference 6. These data are summarized in table III.

3.2.2 Propulsion characteristics.- The propulsion characteristics of the IMRCS were obtained from reference 7. There are four basic uses of the IMRCS: translation, rotation, deadband operation, and moment control. The criteria for IMRCS propellant consumption for these modes are discussed in the following paragraphs.

In the Apollo 5 mission, translation maneuvers require four +X-axis thrusters. The propulsion characteristics of a single RCS thruster are shown in table IV.

For simulation purposes, all orientation maneuvers have been accomplished at a 5-deg/sec rate. However, if the resultant maneuver time is less than 1 second, a maneuver rate of 1 deg/sec was used instead.

For the AS-204/LM-1 mission no control is provided about the spacecraft X-axis. Thus, for all attitude maneuvers dictated by guidance (including prethrust alignment) the axis of rotation is normal to a plane defined by the present spacecraft X-axis and the desired spacecraft X-axis. Thus the X-axis travels through the shortest path to attain a desired attitude. The RCS propellant consumption during unguided attitude orientation maneuvers was taken from reference 8.

During all orbital coasts, the LM is maintained within a specified angular displacement from a desired attitude. The angular displacement may be either the  $\pm 5^\circ$  maximum or the  $\pm 3^\circ$  minimum deadband. The criteria for RCS propellant consumption during deadband operations are given in table V and are also taken from reference 8.

The RCS is also used for moment control during guided descent engine and ascent engine burns. For simulation purposes, one RCS jet was assumed to be thrusting for appropriate lengths of time in a positive grade direction for moment control. The time rate of propellant utilized by the RCS during the DPS-1, DPS-2, and APS-2 burns is given in figures 3, 4, and 5, respectively, and is taken from reference 9.

**3.2.2.1 Descent propulsion system:** The descent propulsion system characteristics have been obtained from reference 6.

The start sequence for the DPS burn consists of an 8-second RCS ullage maneuver which begins 7.5 seconds before DPS engine-on signal is sent and terminates 0.5 second later. It should be noted that when an engine-on signal is sent, thrust does not begin immediately. However, the term ignition will be applied to the time of engine on, and not thrust initiation. Following DPS ignition at the 10 percent throttle setting (1283-lb thrust), the throttle setting is increased to the FTP 26 seconds after ignition. The DPS buildup and tailoff profiles are given in figures 6 and 7, respectively, and are taken from reference 6. Propellant consumption rate as a function of DPS thrust is presented in figure 8.

**3.2.2.2 Ascent propulsion system:** The ascent propulsion system characteristics were also obtained from reference 6.

The start sequence for the APS-2 burn consists of a 13-second RCS ullage maneuver which begins 12.5 seconds before APS ignition and terminates 0.5 second later. The thrust buildup and tailoff characteristics are presented in figures 9 and 10, respectively. The APS thrust and propellant flow rate are given in table VI. Plume impingement effects during the FITH abort test were simulated by applying an impulse of 774 lb/sec to the ascent stage. This datum was obtained from reference 10. The sequence of events concerned with the FITH maneuver were taken from reference 11.

### 3.3 MSFN Stations

The locations and capabilities of the MSFN stations that are planned to be available for support of Apollo 5 mission were obtained from references 12 and 13. These data are summarized in table VII.

## 4.0 MISSION DESCRIPTION

### 4.1 S-IB/S-IVB LM Launch Phase

Launch of Apollo 5 is planned to occur from launch complex 37B of the Kennedy Space Center. For mission simulations, launch is assumed to occur at 14:00 hours G.m.t. (09:00 hours e.s.t.) on January 16, 1968.

A discrete events summary of this mission phase, based on reference 4, is presented in table VIII.

Insertion into elliptic orbit occurs 608.152 seconds after lift-off. The vehicle state vector at insertion is presented in table II.

It should be noted that the data presented for this mission phase are included for completeness only. The official launch vehicle operational trajectory data are presented in the launch vehicle operational trajectory (ref. 4).

### 4.2 S-IVB/SLA/LM Orbital Coast

At S-IVB GCS the S-IVB auxiliary propulsion system initiates a maneuver to maintain the inertial attitude of the S-IVB/SLA/LM. The launch vehicle time base four ( $t_{b_4}$ ) is established by the IU 0.2 second later. S-IVB LOX venting begins 0.2 second after  $t_{b_4}$  and terminates after 40 seconds; LH<sub>2</sub> venting starts 0.4 second after  $t_{b_4}$  and terminates 1260 seconds later. Six seconds after S-IVB/LM orbit insertion, mission phase 6 is enabled. This phase will be disabled 716 seconds later.

The aerodynamic shroud which covered the LM during the ascent-to-orbit mission phase is jettisoned at 00:10:43.35 g.e.t. The aerodynamic shroud is springloaded so that separation imparts a ΔV of 7 fps to the shroud.

Forty-five seconds after shroud jettison, the launch vehicle second stage maneuvers to maintain the spacecraft +X-axis in the local horizontal plane in the direction of motion and the +Z-axis pointing upward along the local vertical. This attitude would place a crew on their backs with heads into the direction of flight in relation to the ground.

Deployment of the SLA occurs at 00:19:58.35 g.e.t. (10 minutes after  $t_{b_4}$ ) southwest of the Canary Island tracking station. Mission phase 6 (S-IVB/IM coast) is disabled at 00:22:10.15 g.e.t.

#### 4.3 S-IVB/IM Separation

The S-IVB/IM will begin an inertial attitude-hold to maintain a constant inertial attitude during the separation sequence at 00:50:05.00. Some 27 seconds later mission phase 7, S-IVB/IM separation, is enabled. Four minutes 22 seconds after the S-IVB begins holding inertial attitude, four IMRCS thrusters are ignited to provide +X-axis translation. Five seconds after RCS ignition, the straps holding the IM in the SLA are mechanically severed, and the IM begins withdrawal from the SLA. Five seconds after the restraining straps are severed, RCS thrusting is terminated. Then, following a 5-second coast, the four +X-axis RCS thrusters are reignited for an additional 5-second burn. Mission phase 7 is then disabled at RCS shutdown.

#### 4.4 Orbital Coast to DPS-1

Twenty seconds after completion of separation, mission phase 8 (DPS cold soak) is enabled. This 150-second mission phase orients the spacecraft to an inertial attitude calculated by the IM. The IM maintains this inertial attitude in the maximum deadband mode for the duration of the subsequent two revolution coasts until 03:55:08.50 g.e.t. when mission phase 9, DPS-1 burn, is enabled.

#### 4.5 DPS-1

A 20-second coast is initiated after mission phase enable, during which the time of DPS ignition and initial thrust attitude are automatically calculated by the IM. This attitude maneuver is performed in order to minimize the attitude transients at the DPS-1 initiation. Four +X-axis RCS thrusters are ignited 7.5 seconds prior to the calculated DPS ignition time (about 262 seconds after mission phase enable) to provide ullage settling. RCS thrusting is then terminated 0.5 second

after the DPS engine is commanded on. Unlike the upcoming DPS-2 burn, steering begins when the DPS engine is turned on. The DPS throttle setting is increased to the FTP, 26 seconds after ignition from the initial 10 percent throttle setting. Guidance cutoff occurs approximately 12 seconds after reaching full throttle.

The "Hohmann descent" guidance technique is used to control the spacecraft attitude to achieve the desired velocity following DPS-1 (ref. 14). This guidance technique exhibits the following characteristics:

1. Burnout at a  $0^{\circ}$  inertial flight-path angle establishing a new line of apsides.
2. Burnout at a velocity such that a desired radius magnitude is achieved after free flight through a central angle of  $180^{\circ}$ .

Following DPS thrust tailoff, mission phase 9 is disabled at 04:00:16.10 g.e.t. The resulting ellipse is 115 and 179 n. mi. (perigee and apogee altitude).

116    179

#### 4.6 Orbital Coast to DPS-2

Following DPS-1, the LM begins an orbital coast to DPS-2. The spacecraft inertial attitude at the end of DPS-1 is maintained in the maximum deadband mode during this coast of approximately 33 minutes.

#### 4.7 DPS-2/FITH/APS-1

4.7.1 Second DPS burn.- Mission phase 11 (DPS-2/FITH/APS-1) is enabled at 04:33:00.3 g.e.t. During the following 25-second coast, the LM is using the engine-on algorithm and powered landing guidance to compute an ignition time and initiate thrust direction. This attitude maneuver is performed in order to minimize the attitude transients at DPS-2 initiation. Approximately 220 seconds after mission phase enable, an 8-second RCS +X-axis translation maneuver is initiated to provide ullage settling which terminates 0.5 second after DPS ignition.

The DPS-2 thrust profile represents the profile expected for lunar landing, which consists of five phases: start sequence, braking, high gate, visibility, and the random throttling sequence. This is provided by the powered landing guidance (ref. 14) which controls thrust vector magnitude and direction. This guidance philosophy utilizes multiple target phases and target parameter sets. These target parameter sets are defined in inertial space by specification of a unit normal to a plane to be achieved at cutoff. This plane forms a  $15.5^{\circ}$  angle with

respect to the initial orbit plane and the line of intersection is about 23° away from the radius at DPS-2 ignition. As noted previously, the spacecraft maintains a constant inertial attitude during the DPS-2 start sequence and guidance-steering is not initiated until the throttle is set to the FTP.

The random throttling sequence, the FITH abort test and the first APS burn are performed in an attitude-hold mode with the thrust vector normal to the target orbit plane. The random throttling phase has throttle settings lasting 10 seconds each at 10, 50, 30, 40, and 20 percent thrust levels. The throttle position will then be increased to maximum throttle in preparation for the FITH. The DPS-2 duration is 12 minutes 34 seconds. The majority of the 7000-fps  $\Delta V$  is directed out of the orbit plane in order to optimize ground coverage of APS-2. The orbit resulting from DPS-2 has a predicted perigee altitude of 165 n. mi. and an apogee altitude of 172 n. mi.

4.7.2 FITH/APS-1.- The FITH abort test is initiated immediately upon completion of the DPS-2 random throttling with almost simultaneous DPS shutdown, IM staging, and APS ignition. Upon detection of the abort stage sequence initiate signal, the DPS engine is commanded off. A time delay of 0.447 second is used to allow the DPS engine thrust to decay to a level that will allow separation. At this time, physical separation takes place and the descent stage is jettisoned. A 0.21-second coast takes place before the APS is commanded on (ref. 11). For this simulation, 774 lb/sec of impulse were applied to the ascent stage during the abort test to simulate plume impingement effects. The APS engine is commanded off 5 seconds later. Mission phase 11 is disabled 0.3 second later after APS tailoff at 4:49:28.76. At APS burn shutdown, the resulting orbit is 167 by 177 n. mi. Specific events during the DPS-2/FITH/APS-1 sequence are illustrated in figure 11.

#### 4.8 Orbital Coast to APS-2

Following the APS-1 shutdown, the IM begins an orbital coast to DPS-2. The inertial attitude of the spacecraft at the end of APS-1 is maintained in the maximum deadband mode during this coast of approximately 1 hour 23 minutes.

#### 4.9 APS-2

Following acquisition by the Coastal Sentry Quebec during the fourth revolution, mission phase 13 is enabled at 06:12:23.23 g.e.t. A 20-second coast is then initiated, during which an initial thrust direction is calculated to minimize attitude start transients at the beginning of APS-2. An attitude maneuver is then performed to orient

the IM to this altitude. The RCS +X-axis thrusters are ignited for 13 seconds to provide ullage settling 157.5 seconds after mission phase enable. The APS-2 engine-on command is sent 12.5 seconds after RCS ignition is initiated.

The ascent guidance logic (ref. 14) is used to control the spacecraft attitude during this powered maneuver. The ascent guidance simulates a lunar ascent trajectory by satisfying two requirements:

1. The spacecraft must reach a specific position in space.
2. This spatial position vector must be reached at a specified time.

Spacecraft radius magnitude, velocity vector, and flight-path angle at predicted cutoff are determined by the ascent guidance to confirm that the intercept requirements are achieved. Nine seconds after APS burn initiation, an RCS interconnect test is initiated to determine the operation of RCS using propellants fed from the APS tanks. This test is terminated 342 seconds after APS ignition. It should be noted that only the RCS is used for ascent stage attitude control and stabilization during this burn.

This burn is specifically targeted so that the APS fuel available for impulse will be depleted prior to the time of guidance commanded shutdown, some 60 seconds away. Also, the instantaneous perigee altitude will not drop below 149 n. mi. to provide for alternate mission capabilities in case of premature APS shutdown. As for DPS-2, the majority of the  $\Delta V$  expended during the 438-second APS-2 (about 6800 fps) is directed out of the orbital plane.

#### 4.10 Post-APS-2 RCS Tests

The Apollo 5 mission is essentially complete at this time; however, additional spacecraft tests are scheduled. Only tests that affected the trajectory (namely, RCS tests) were incorporated in this simulation.

All the RCS tests will utilize only two +X-axis thrusters except the fifth test which will use four +X-thrusters. The RCS will also be used to provide attitude control during powered flight (ref. 8).

Following acquisition by the Rose Knot Victor during the sixth revolution, the IM will be oriented so that the thrust axis is in the orbit plane and about  $45^\circ$  above the local horizontal in preparation for the first RCS burn test. This 4-minute 14-second burn is designed to deplete the RCS propellant available for impulse in tankage system B and verify the RCS thrusters under a long-duration burn.

After RCS shutdown, the vehicle then maintains inertial attitude in the minimum deadband mode until acquisition by Texas. The IM will then be commanded to an orientation such that the thrust vector is normal to the orbit plane and in the local horizontal for the second RCS burn test. This 45-second RCS burn is to investigate the effects of helium ingestion into the RCS propellants on RCS thruster and DAP operation.

After RCS shutdown, the vehicle maintains inertial attitude in the minimum deadband until acquisition again by Texas late in the seventh revolution. Another RCS helium ingestion test (third RCS test) will then be performed for 45 seconds in the same inertial attitude as the previous test. The spacecraft will then coast for 180 seconds and the RCS thrusters reignited for 10 seconds. This fourth RCS burn test will investigate RCS thruster operation after maximum soak back from previous thruster operation. This test should be conducted within 180 seconds after previous thruster operation of greater than 15 seconds.

The IM will then coast until acquisition by Hawaii in revolution 8. An erroneous ascent stage weight will then be updated to the IM and four RCS thrusters ignited to deplete tankage system A. This 50-second burn will verify the response of LGC attitude control with an erroneous vehicle weight in LGC memory. It will also determine the RCS usage for attitude control under these conditions.

All RCS tests will utilize only two +X-axis thrusters except the fifth test which will use four +X-thrusters.

This concludes the planned powered-flight maneuver tests for Apollo 5. An additional revolution has been added after the fifth RCS test to provide data for planning any additional spacecraft testing.

Table IX presents a detailed summary according to mission event, ground elapsed time, position, velocity, total spacecraft weight, DPS or APS and RCS propellant consumed,  $\Delta V$ , and significant orbital parameters. The RCS propellant consumption reflects that used in reference 8. Table X presents a summary of MSFN coverage during the mission for a minimum elevation angle of  $5^\circ$  and a maximum slant range of 750 n. mi. Table XI presents the same data for  $0^\circ$  and 32 000 n. mi. Figure 12 presents the ground tracks for the nominal mission. Table XII presents the computed matrix necessary to transform vectors from the IMU system to the Greenwich ECI system. It also contains the matrix REFSMMAT, which transforms vectors from the IMU system to the spacecraft Besselian ECI system. Table XIII contains the targets generated and utilized by the Lunar Landing Branch to simulate the nominal mission.

TABLE XIII.- MATRICES USED IN THE OPERATIONAL TRAJECTORY  
FOR VECTOR CONVERSION

REFSMMAT<sup>a</sup>

$$\begin{bmatrix} -.65568236 & -.39013053 & +0.64643547 \\ +.37964854 & -.91041273 & -.16436435 \\ +.65264664 & +.13764747 & +.74505405 \end{bmatrix}$$

TI2SM<sup>b</sup>

$$\begin{bmatrix} -.083009347 & +.75843959 & +.64643547 \\ -.98587430 & +.032189984 & -.16436435 \\ -.14546918 & -.65094789 & +.74505405 \end{bmatrix}$$

$$^a [\bar{x}]_{IMU} = [REFSMMAT] [\bar{x}]_{BES}$$

$$^b [\bar{x}]_{IMU} = [TI2SM] [\bar{x}]_{ECI}$$

IMU = Inertial measurement unit system (stable member, or inertial platform)

BES = Reference computation system for spacecraft. An earth-centered inertial system with the X-axis in the direction of the vernal equinox at the beginning of the Besselian year nearest the launch date

ECI = Reference computation system for trajectory simulation. An earth centered inertial system with the X-axis in the Greenwich meridian at midnight before launch. (Launch is assumed to be on January 16, 1968, 14:00 hr GMT)

TABLE XIII.- APOLLO 5 SPACECRAFT TARGETS AND EVENT TIMES  
USED IN THE OPERATIONAL TRAJECTORY

|  |             |  |
|--|-------------|--|
| Mission phase 9 enable                 |             |  |
| time, hr:min:sec, g.e.t. . . . .       | 3:55:08.50  |  |
| R <sub>PP</sub> , ft . . . . .         | 22 000 000  |  |
| Mission phase 11 enable                |             |  |
| time, hr:min:sec, g.e.t. . . . .       | 4:33:00.30  |  |
| CPT6 <sub>ECI</sub>                    |             |  |
| X, n.d. . . . .                        | +0.48278786 |  |
| Y, n.d. . . . .                        | +0.06931671 |  |
| Z, n.d. . . . .                        | +0.87298972 |  |
| Mission phase 13 enable                |             |  |
| time, hr:min:sec, g.e.t. . . . .       | 6:12:23.3   |  |
| TGONOM, sec . . . . .                  | 515.6       |  |
| RDOTD, fps. . . . .                    | -90.371376  |  |
| YDOTD, fps. . . . .                    | 24 891.905  |  |
| ZDOTD, fps. . . . .                    | 7747.6129   |  |
| R̄ <sub>CSM ECI</sub>                  |             |  |
| X, ft . . . . .                        | 22 571 889  |  |
| Y, ft . . . . .                        | -4 848 133  |  |
| Z, ft . . . . .                        | -5 894 065  |  |
| R <sub>CO</sub> , ft . . . . .         | 21 938 132  |  |
| T <sub>INT</sub> , sec, g.e.t. . . . . | 24 880      |  |
