FOREWORD

The primary avionics software system (PASS) requirements for the computer programs that execute in the Shuttle general-purpose computers (GPCs) are specified in the Computer Program Development Specifications (CPDSs) and the Functional Subsystem Software Requirements (FSSR) documents. The requirements are specified at three levels:

Level A CPDS – System-level constraints and capabilities

Level B CPDS – Functional requirements

Level C FSSR – Detailed-level requirements

The Level A CPDS specifies system-level constraints and capabilities that are not oriented toward any particular program end item. The Level B CPDS specifies system-level requirements for guidance, navigation, and control (GN&C) and detailed requirements for systems management (SM) and vehicle utility (VU). The Level C FSSRs specify the detailed requirements for GN&C and display/controls. The Level C reconfigurable requirements are specified in the systems management and payload documents. The Level A, Level B, and Level C requirements documents are listed in Section 2.0, Applicable Documents.

DOCUMENT CHANGE RECORD

The following tabulation summarizes the change activity associated with this document.

DOCUMENT CHANGE RECORD		
Issue and Date	Change Summary/Effectivity	
OI-34 Release December 14, 2007	This baseline release for effectivity OI-34 and subs includes: <u>CR</u> <u>OI</u> <u>Title</u> 93017G 33 Baseline RSS99D0100 with Expanded Downlist	

This page intentionally left blank.

CHANGE REQUEST SUMMARY

The following tabulation lists the paragraphs, tables (T), and figures (F) that have been changed as a result of approved change requests for this release. Changes incorporated prior to this release are listed in Appendix R. Changes from approved change requests (CRs) to this document are indicated by a change bar in the outer margin of the changed page.

CHANGE REQUEST SUMMARY			
Paragraph	CR No.	OI	CR Title
1.3-1.(T)	93017G	33	Baseline RSS99D0100 with Expanded Downlist
4.4.5-1.(T)	93017G	33	Baseline RSS99D0100 with Expanded Downlist
4.4.5-2.(T)	93017G	33	Baseline RSS99D0100 with Expanded Downlist

1.0 INTRODUCTION

1.1 PURPOSE

The purpose of the Flight Control (FC) Level C document is to present the requirement details and formulations of the FC Level B functional requirements for the integrated vehicle GN&C flight software.

1.2 SCOPE

This document contains the requirement details and formulations for those FC functions which are operative during the transition phase of flight. The FC functions are those specified in the GN&C Level B functional requirements document.

1.3 ORGANIZATION

This document is organized into the following sections:

- 1.0 Introduction
- 2.0 Applicable Documents
- 3.0 Overview
- 4.0 Flight Control Functional Requirements

Section 1 defines the purpose, scope, and organization of this document. Section 2 lists the applicable documents. Section 3 provides an overview of the OFP software functions and discusses the contents of Section 4. Section 4 specifies the requirement details. It also contains applicable tables (Interface Definition Document (IDD) inputs/outputs, I-Loads, K-Loads, and Constants) located at the end of each Principal Function.

The automated IDD tables provided herein define signal (parameter) interface requirements either between hardware (LRU) and software elements or between software elements and other software elements. A GN&C software element is either a sequenced principal function (PF), crew generated specialist/display function, or an OPS display function. In the event of a conflict between the IDD tables and other internal text input/output tables, the SASCB data base-controlled IDD tables take precedence.

The following table defines the data elements found in the IDD input/output, I–Load, K–Load, and Constant tables for each principal function.

Table 1.3-1. Parameter Element Description												
Title	Definition	Valid Entries										
CAT	Category of the I–Load (**Note)	Three alphanumeric characters: the first character must be alphabetic.										
D	Dependency of the I–Load	D = Design M = Mission L = LRU										
DESCRIPTION	Parameter description of the K–Load or Constant.	A string of ≤ 64 characters.										
DESTINATION	Destination of the output parameter	Abbreviated functional titles. (**Note)										
DT or DATA TYPE	Data Type	<ul style="list-style-type: none"> * See reference (1) for valid I–Load, K–Load and Constant data types. * See reference (2) for valid IDD data types for parameters with destination TLM. * See reference (3) for valid IDD data types for all other parameters. 										
ENG UNITS or UNITS	Engineering Units	<ul style="list-style-type: none"> * See reference (1) for valid I–Load, K–Load and Constant units. * See reference (2) for valid IDD units for parameters with destination TLM. * See reference (3) for valid IDD units for all other parameters. 										
FSSR NAME	Requirements parameter name	A string (with no embedded blanks) of ≤ 32 characters consisting of alphanumerics, underscores, parenthesis, commas and slashes. Parenthesis are used for array elements. Commas separate the different indices of multidimensional arrays. Slashes are used to separate multiple names used for a single MSID.										
LAST CR	The last CR affecting the parameter	5 digit number with an alphabetic revision letter.										
MC	Memory Configuration	<table style="width: 100%; border-collapse: collapse;"> <tr> <td style="width: 50%;">00=Generic</td> <td style="width: 50%;">05 = SM4 Orbit P/L</td> </tr> <tr> <td>01=GN1 Ascent/GN6 RTLS</td> <td>06 = P/L9 MMU</td> </tr> <tr> <td>02=GN2 Orbit</td> <td>07 = Not Assigned</td> </tr> <tr> <td>03=GN3 Entry</td> <td>08 = GN8 On–Orbit C/O</td> </tr> <tr> <td>04=SM2 On–Orbit</td> <td>09 = GN9 Preflight</td> </tr> </table>	00=Generic	05 = SM4 Orbit P/L	01=GN1 Ascent/GN6 RTLS	06 = P/L9 MMU	02=GN2 Orbit	07 = Not Assigned	03=GN3 Entry	08 = GN8 On–Orbit C/O	04=SM2 On–Orbit	09 = GN9 Preflight
00=Generic	05 = SM4 Orbit P/L											
01=GN1 Ascent/GN6 RTLS	06 = P/L9 MMU											
02=GN2 Orbit	07 = Not Assigned											
03=GN3 Entry	08 = GN8 On–Orbit C/O											
04=SM2 On–Orbit	09 = GN9 Preflight											
MSID or M/S ID	Measurement/Stimulus Identification	Maximum of 10 alphanumeric characters. * See reference (3) for specifications										
NOMENCLATURE	Parameter description of the IDD parameter.	String of ≤ 34 characters (including underscores and blank spaces).										
PR or PREC	Precision	D, DP =Double S, SP =Single										
SOURCE	Origin of the input parameter	Abbreviated functional titles.										

Table 1.3-1. Parameter Element Description

Title	Definition	Valid Entries
S	Software Utilization	C = Common B = BFS Unique P = Primary X = BFS Derived A = BFS Converted
PR FCTN	Cross reference of the principal function identifiers that are applicable to this parameter.	See Level B GN&C CPDS SS-P-0002-510
VALUE	The value of the K-Load or Constant	* See reference (1) for valid value formats.
REV	Revision indicator	An Asterisk (*) indicates changes for the current OI version.
<p>* References: (1) JSC 19350 I-Load Requirements Document Volume I (2) SS-P-0002-140 Level A SS Downlist/Uplink CPDS (3) JSC 18206 Shuttle Data Integration Plan Volume III MAST II/STAR Deliverable Products.</p> <p>** Note For additional information on any I-Load, contact the I-Load owner defined in CR 98032, JSC, USA, and Boeing I-Load Owner Assignments</p> <p>*** Note IDD output (source) tables which reflect parameters going to input (destination) "TLM" shall not be interpreted as a signal actually being downlisted. The parameter is only available for downlist in COMPOOL and does not appear in a downlist format. Parameters actually on the downlist will be designated with a destination denoting the downlist Format with a Rate Code. The Rate Code legend appears at the end of each FSSR data table. To complete the downlist information, Parent MSIDs (indicated by a 'P' in the 9th character of the MSID) are now included in the software function output data tables in which a Child MSID already appears. A Parent MSID will have the same downlist destinations as its Child(ren) MSID(s).</p>

In the event of a conflict between the documents referenced herein and the contents of this specification, the precedence shall be determined as defined in paragraph 1.3 of CPDS SS-P-0002-170, Volume 1, System Level Requirements, Software.

3.0 OVERVIEW

3.1 OPERATIONAL FLIGHT PROGRAM

The Operational Flight Program (OFP) represents the total computer program which operates in the orbiter general-purpose flight computer subsystem. The requirements for each OFP are specified at three levels: system-level (A), functional-level (B), and detail-level (C) requirements. In addition, the Level B and C requirements are specified in separate documents for guidance, navigation, and control (GN&C); for system management (SM), and for vehicle utility. This document is the flight control (FC) part of the GN&C Level C OFP requirements for the transition flight phase.

3.2 GN&C SOFTWARE MAJOR FUNCTIONS

The orbiter general-purpose computers (GPCs) provide the following GN&C major functions:

- A. Guidance
- B. Navigation
- C. Flight control
- D. Redundancy management/moding, sequencing, and control
- E. Subsystems operating programs
- F. Display interface processor

Additional GN&C major functions provided by the GPC software are the flight computer operating system, GN&C system management and performance monitoring, and checkout.

This document specifies the software functional requirements for the GN&C flight control major function.

3.3 FLIGHT CONTROL SYSTEM OVERVIEW

In this FSSR release, the detailed functional requirements are presented for the following principal function:

- Transition DAP

The flight control (FC) module can be thought of as containing a hierarchy of modules, the top level of which is shown in Figure 3.3-1.

Subsection 4.4 presents the detailed functional requirements for the Transition DAP module shown in Figure 3.3-1. These requirements include constraints on execution times, delay times, cycle frequencies, and module sequencing order.

3.4 TRACEABILITY

Table 3.4-1 shows the traceability of the software paragraphs in this FSSR with respect to the corresponding Sections of the Level B CPDS' documentation. In addition, table 3.4-2 shows the

traceability of the PASS GN&C principal functions located in this FSSR with respect to the applicable BFS paragraphs in the Level C PRD specifications. These tables are provided for information only.

Table 3.4-1. Level B to Level C Traceability

4.201	Transition Digital Autopilot (TRANS DAP)	4.4

Table 3.4-2. Transition Digital Autopilot FSSR/PRD Correlation					
Principal Function	FSSR Paragraph	FSSR Title	BFS PRD	PRD Paragraph	BFS Title
G4.201	4.4	Transition DAP Functional Requirements	MG038105	3.2.4.4	Transition Digital Autopilot (T_DAP)

3.5 DOCUMENTED REQUIREMENTS PRECEDENCE

Requirements precedence in this document shall be as follows:

1. If there is a conflict between the data in the function subtables and the standard principal function tables, the principal function tables shall have precedence.
2. If there is a conflict between the data in the flow diagrams and the written requirements, the written requirements shall have precedence.

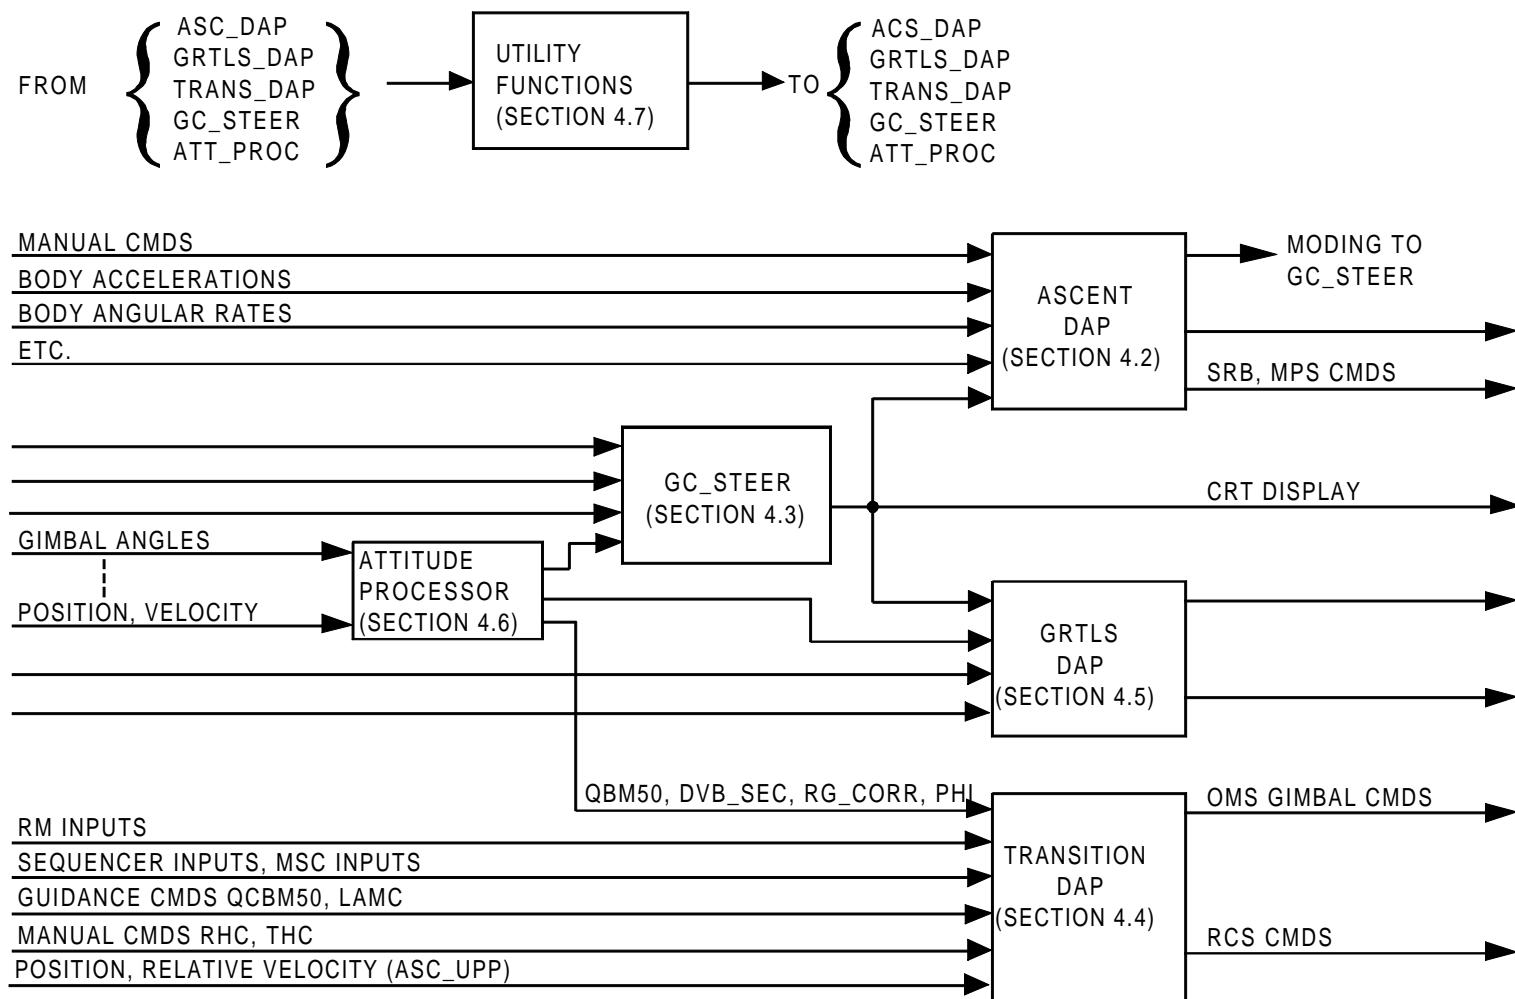

FIGURE 3.3-1. Ascent Phase Flight Control High-Level Organization

4.4 TRANSITION DIGITAL AUTOPILOT (DAP) (G4.201) FUNCTIONAL REQUIREMENTS

4.4.1 Introduction

The flight control (FC) module controls the vehicle in response to either automatic or manual commands during the insertion (OPS 1) and deorbit (OPS 3) flight phases. The effectors used to produce control forces and moments on the vehicle are the OMS engines and primary RCS jets. When the OMS engines are firing, the main control mode is engine thrust vector control (TVC); but the RCS jets are also available to provide additional control authority (e.g., to cover a single OMS engine failure).

4.4.2 Interface and K-Load Requirements

The interface requirements for the transition DAP are given in Tables 4.4.2–1 and 4.4.2–2. Table 4.4.2–1 lists the input variables, including some that are K–loads for the insertion phase and some that are carryovers from the on–orbit phase (OPS 2) for use in the deorbit phase. (Some input variables have both attributes.) Table 4.4.2–2 lists the output variables. Update rates and sample rates in Tables 4.4.2–1 and 4.4.2–2 mean, respectively, the rate at which a parameter is assigned and the rate at which it is referenced. Thus, the update rates in Table 4.4.2–1 and the sample rates in Table 4.4.2–2 are rates at which functions interfacing with the DAP are expected to perform their I/O operations. In both of these tables, the MSID column gives an identifying code. For multi–element variables (such as arrays, vectors, or structures) of reasonable size, one code is given for each element. The order of listing of the codes corresponds to a certain order of elements. This ordering is given parenthetically below the codes, is included in the description column, or is understood to be X, Y, Z or roll, pitch, yaw, whichever applies.

Table 4.4.2–3 lists the I-load/K–load/constants used by the Transition DAP.

Table 4.4.2-1. Input Parameters for the Transition DAP Module								
Name	Description	MSID	Source	Type	Range	Unit	Sample Rate (Hz)	Update Rate Req'd (Hz)
Crew Variables								
OMS_PITCH_TRIM	OMS engines pitch trim angle with respect to center of gimbal travel	V93H6915C	See Note 1; also XXXXX MNVR YYYYYY (6.35), U/L	S	-10 to 10	deg	12.5	
OMS_YAW_TRIM	Left and right OMS engines yaw trim angles with respect to center of gimbal travel	V93H6916C V93H6918C	See Note 1; also XXXXX MNVR YYYYYY (6.35), U/L	A(2)S	-10 to 10	deg	12.5	
Display Data								
Q_B_I_CMD	Commanded vehicle attitude with respect to reference attitude, given as the M50-to-body quaternion	V94U3980C V94U3981C V94U3982C V94U3983C	AS MNVR DIP (4.210) or DEORB MNVR DIP (4.211); ORB I NS GUID (4.3) or DEORB GUID (4.209)	Struct: S; V(3)S	0 to 1; -1 to 1	none	12.5	1/maneuver, 1.04
Effector Fault Flags								
AVAILABLE_JET_AFT	AFT jet available status (1 = available)	V90X4520X to V90X4531X, V90X4534X to V90X4545X (PRCS only)	RCS RM (4.91)	A(28)B	0, 1	none	12.5	12.5
AVAILABLE_JET_FWD	Fwd jet available status (1 = available)	V90X4548X to V90X4561X (PRCS only)	RCS RM (4.91)	A(16)B	0, 1	none	12.5	12.5
JET_FAIL_CHANGE_FLAG	Flag signifying change in HFAIL (1 = changed)	V90X4619X	RCS RM (4.91)	B	0, 1	none	12.5	12.5
JET_MAP	Mapping of jet use preference within groups	V90J5727C to V90J5764C	RCS RM (4.91) or carry-over from previous OPS	A(38)I	1-28	none	12.5	12.5

Table 4.4.2-1. Input Parameters for the Transition DAP Module								
Name	Description	MSID	Source	Type	Range	Unit	Sample Rate (Hz)	Update Rate Req'd (Hz)
Guidance Commands								
LAMC	Commanded vehicle velocity-to-go unit vector in reference coordinates	V90U1954C V90U1955C V90U1956C	ORB INS GUID (4.3) or DEORB GUID (4.209)	V(3)S	-1 to 1	none	1.04	0.52
LAMDC	Commanded derivative of LAMC in reference coordinates	V90U1957C V90U1958C V90U1959C	ORB INS GUID (4.3) or DEORB GUID (4.209)	V(3)S		1/s	1.04	0.52
TLAMC	Time of issuance of LAMC command, expressed as GMT	V90W1953C	ORB INS GUID (4.3) or DEORB GUID (4.209)	S	0 to 1.0E07	s	1.04	0.52
HC Commands								
RHC	Rotational hand controller deflection	V96H0005CB V96H0007CB V96H0004CA	3-AX RHC SOP (4.171)	A(3)S	-50 to 50	deg	12.5	12.5

4.4.3 Overview and Functional Description

A high-level diagram (Figure 4.4.3-1) shows the major sections of the Transition DAP. The transition FC system converts automatic and manual maneuver commands (from the insertion or deorbit guidance algorithms or from the crew) to OMS engine deflections and RCS jet firings by utilizing attitude rate feedback from the rate gyros, and attitude feedback and velocity increments from the IMU via the attitude processor module. As shown in the figure, the Transition DAP consists of two major subsections: the reconfiguration logic and the control laws. The control law section is composed of three subsections: the steering processor, the RCS processor, and the OMS processor.

A. Transition Reconfiguration Logic (TRNS_RECON). This logic controls the modeing, sequencing, and initialization of the control law modules by processing inputs from other principal functions. It also sets gains, deadbands, and rate limits for the control law module.

B. Steering Processor. This subfunction is an interface between the steering commands from the insertion or deorbit guidance functions and the Transition DAP. It also processes manual command inputs, provides commands for the -Z-axis separation maneuver at ET_SEP, and provides attitude error information for display.

C. RCS Processor. This subfunction generates the RCS jet commands required to produce the commanded vehicle translations and rotations. Its primary inputs are attitude and rate error signals from the steering processor, although there is a manual input acceleration mode. Additional inputs are deadbands, rate limits, etc. The outputs are individual jet commands, as well as data to other principal functions.

D. OMS Processor. This subfunction generates the OMS engine actuator commands required to gimbal the engines and produce the desired vehicle/engine attitude and thrust direction. Its primary inputs are the attitude rate commands from the steering processor, along with rate gyro feedback signals and initial engine trim values. There are also discrete inputs for initialization and gain changing. The outputs are the OMS engine actuator commands, as well as the engine trim values for display.

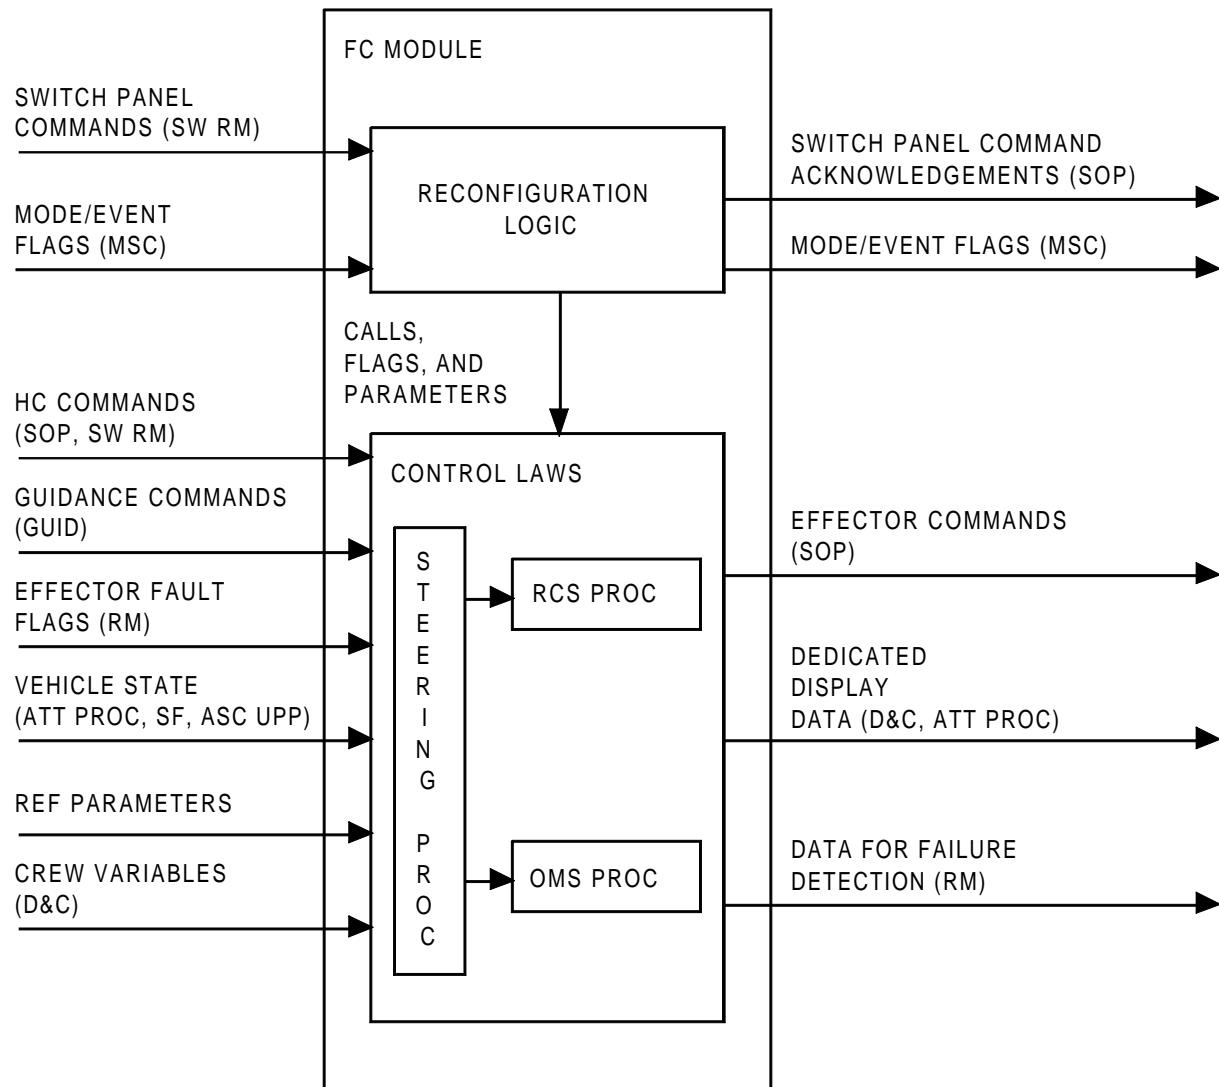

FIGURE 4.4.3-1. Relationship of FC Module Reconfiguration Logic and Control Laws

4.4.4 Detailed Functional Requirements

4.4.4.1 Reconfiguration Module (TRNS_RECON).

4.4.4.1.1 Function.

The primary function of TRNS_RECON is to call the various modules of the TRNS_DAP in their proper sequence. This sequence is determined by checking parameters that define the current operating mode. It is also the function of TRNS_RECON to specify configuration-dependent parameters, such as rates and gains; set initialization flags when required; set up the signals to light panel lamps; keep a clock to time the processing of “slow” modules; and perform certain “housekeeping” operations.

The inputs to TRNS_RECON are used to determine how the modules of the Transition DAP should be strung together to perform the desired processing. Table 4.4.4.1.1-1 describes the positions of the switches of Figure 4.4.4.2-1 in terms of these inputs. The switches in this diagram control data flow among the function modules; their positions define which modules are needed and, to an extent, their sequencing requirements. If, with a given switch configuration, module A’s outputs are not received anywhere, then module A is not needed. Also, if module B drives only module A, it too is not needed. Generally, if B drives A and both are needed, B should precede A; however, exceptions can be found, such as one-cycle delays in Figure 4.4.4.2-1. These one-cycle delays occur when a downstream module must pass information back to an upstream module. The upstream module will not be able to process the new information until the following pass. Logical combinations of controlling inputs required for each switch position are given in the table.

4.4.4.1.2 Moding and Sequencing.

Attitude control for the Transition DAP will be performed in one of two modes, TVC or RCS. However, the RCS processor will run during both the RCS and TVC modes. Translation control by the RCS processor will be active at all times. The control modes may be broken down into a number of submodes that are defined in terms of moding inputs. These modes are defined in Table 4.4.4.1.2-1. This table serves as an index to Figure 4.4.4.1.2-1, which gives the module-by-module sequencing requirements for each listed mode.

The diagrams of Figure 4.4.4.1.2-1 are read vertically from top to bottom. Requirements for sequential execution are indicated with solid-line arrows. For those cases in which two or more modules are at a given level, there is no execution sequencing requirement. For example, in diagram I.A.1., TVC_LAW_ROLL must be executed before TVC_MIXER in a given cycle; similarly, TVC_LAW_PITCH_YAW must be executed before TVC_MIXER. However, there is no requirement as to the execution sequence of TVC_LAW_ROLL with respect to TVC_LAW_PITCH_YAW. (Later developments may indicate that transport delays might be alleviated by executing one or the other of these first, but this document does not deal with such considerations.)

It should be noted that ROT_ACCEL and TRANS_ACCEL_TRANSITION are treated as modules in Figure 4.4.4.1.2-1, although they are simple unity gains and, therefore, not described in Subsection 4.4.4.2.

In general, the sequential execution requirements are determined by the data flow requirements between OFC modules. There are some cases, however, in which the outputs of one module may overwrite the outputs of another. Consequently, the order in which these modules are processed is important; and this relationship is indicated by the use of a dashed line in the diagram.

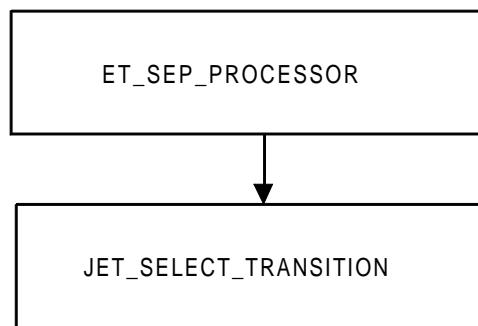

FIGURE 4.4.4.1.2-1.(6) Control Law Function Module Sequencing Requirements (Sheet 6 of 6)

4.4.4.1.2.1 TVC Attitude Control.

The TVC mode is entered when an ON command is present for one or both OMS engines. Six submodes exist, depending on the number of OMS engines burning, whether auto or manual has been selected, and on the position of the RHC. The processing requirements differ for each submode, as indicated in Table 4.4.4.1.2-1 and Figure 4.4.4.1.2-1.

It is assumed that for a two-engine burn, the ON commands for both engines will be turned on together and off together.

TRNS_RECON will configure for a two-engine burn if an ON command is present for both engines. If one of the ON commands is turned off during a two-engine burn for any reason, TRNS_RECON will automatically reconfigure the TRANS_DAP to one-engine status. The transition DAP does not prevent nor is it required to support a reversal of this reconfiguration during the remainder of the burn. It is possible to make a nominal one-engine burn, whether or not the unused engine has failed.

The crew may choose to perform the OMS burn under automatic or manual control by means of the AUTO/INTRL PBIs. Changes from auto to manual or manual to auto are allowed at any time. Manual submodes may also be selected by moving the RHC out of detent. The TRNS_DAP will then remain in manual until the RHC is returned to detent and the AUTO PBI is depressed.

The auto submodes are determined on the basis of engine status (two engines or one engine). The RCS processor will run while the OMS processor is running during all auto submodes.

The manual submodes are determined on the basis of engine status and RHC position. The nominal manual mode will be proportional rate command, processed by the MANUAL_TVC module of the steering processor. The RCS processor will be driven by MANUAL_TVC except in the following cases:

- a. If the soft stop for a given axis is exceeded, then that axis is downmoded to the ACCEL submode. The other axes are not affected. This submode passes RHC commands straight to JET_SELECT_TRANSITION and bypasses the phase plane. Moding returns to proportional rate command when the RHC is no longer deflected beyond the soft stop.
- b. Discrete rate command/attitude hold will be provided during single-engine burns for the roll axis only. If soft stop for the roll axis is exceeded, the roll axis is downmoded to acceleration command. Moding returns to discrete rate command/attitude hold upon the return of the RHC to detent. This scheme allows for a free drift about the roll axis while the RHC is between detent and the soft stop.

4.4.4.1.2.2 RCS Attitude Control.

The RCS mode is entered in the absence of an ON command for either OMS engine. Selection of the automatic or manual mode of RCS attitude control is a function of PBI selection and RHC “hot stick” downmoding. The automatic mode is entered when the DAP AUTO PBI is pressed with the RHC in detent. TRNS_RECON selects a target attitude, and AUTO_MNVR performs the maneuver and/or attitude hold. This mode implements an attitude hold by selecting the target attitude as the existing attitude upon a mode change from manual to automatic or vice versa, so long as a guided RCS burn is not under way, upon first pass insertion and deorbit, upon ET SEP initiation, and upon completion of an OMS burn. Also, if the PREBURN_MNVR flag is set on during automatic mode, the target attitude is the attitude commanded by the XXXXX MNVR YYYYYY display. If the target attitude is a displacement of more than AMM from the current attitude, an automatic maneuver will precede the attitude held. If the PREBURN_MNVR flag is

set on during manual mode, the flag is ignored. As long as the target attitude is identical with the commanded attitude on the XXXXX MNVR YYYYY display and AUTO_MNVR is active, the MNVR_IN_PROGRESS flag is on to indicate that the autopilot is automatically tracking the displayed attitude. If the commanded attitude is changed while the MNVR_IN_PROGRESS flag is on, the flag will be set off. Additionally, if maneuvering, the maneuver is terminated and attitude hold is established at the existing attitude. The target attitude is sent to A/E ATT_PROC as the display attitude pre-MM 104. Upon entering MM 104 and thereafter, the commanded attitude, Q_B_I_CMD, is sent to the A/E ATT_PROC as the display attitude. The manual mode is entered if the DAP INTRL PBI is pressed or the RHC is moved out of detent. If a preburn maneuver was in progress at the time of the mode change, it cannot be resumed simply by remodelling to automatic; the PREBURN_MNVR flag must be turned ON again by the XXXXX MNVR YYYYY display. In the manual mode, the TRANS_DAP may be configured in the discrete rate command/ attitude hold submode or the pulse submode through axis-by-axis PBI selection. If the soft stop is exceeded for a given axis, control for that axis is downmoded to acceleration command. Moding returns to the previously selected submode upon return of the RHC to detent. This scheme allows for a free drift about the downmoded axis while the RHC is between detent and the soft stop.

For a time interval equal to DRIFT_TIME after receipt of the ET separation command, SEP_MINUSZ_CMD, there is no RCS attitude control; i.e., all three body rotation axes are in free drift. The free drift is implemented without reconfiguring by zeroing the rotation command ROT_JET_CMD while rotation control modules dictated by the current mode continue to execute. Attitude control is resumed by allowing ROT_JET_CMD to pass unchanged after expiration of DRIFT_TIME. Since no module initializations occur upon resumption of attitude control, the attitude hold reference continues to be the attitude of the vehicle at the time SEP_MINUSZ_CMD was set, assuming a closed loop mode (manual discrete/attitude hold or auto) is in use.

4.4.4.1.2.3 Translation Control Mode.

The TRNS_DAP is in a manual translation acceleration command submode at all times except during an automatic -Z maneuver, which will be active from the time that the SEP_MINUSZ_CMD is received until the separation is complete. TRNS_RECON will set [TRANS_JET_CMD] to [0,0,0,0,0,1] upon receipt of SEP_MINUSZ_CMD. If the THC is moved from detent during this maneuver, automatic -Z commands will no longer be issued. The override is not reversible, and the manual acceleration command submode will take over. However, the ET_SEP_PROCESSOR will continue to run until the SEP_COMPLETE flag is turned on. If the THC is then returned to detent before the SEP_COMPLETE flag is turned ON, TRNS_RECON will set the SEP_COMPLETE flag to ON at the start of the ensuing OMS burn.

4.4.4.1.3 Other TRNS_RECON Functions.

- a. Set module initialization flags. TRNS_RECON will set the initialization flags used by the control law modules. The names of the flags and the conditions for setting them are given in Table 4.4.4.1.3-1.
- b. OMS gimbal trim. TRNS_RECON must initialize and call the module TVC_LAW_PITCH_YAW to trim the OMS engines. TRNS_RECON will cause a gimbal trim to occur whenever either of the following two events takes place:

- (1) The TRIM_OMS_GIMBALS flag is ON and an OMS burn is not in progress. TVC_LAW_PITCH_YAW will be initialized and executed each pass while this flag is set. The trim values are K-load values or the K-load values updated by the crew or the trim integrator during a burn.
- (2) One OMS engine has been shut down during a two-engine burn. TRNS_RECON will initialize TVC_LAW_PITCH_YAW at the time of shutdown. Execution of TVC_LAW_PITCH_YAW will continue without interruption. The trim values will be taken from a K-load.

(OMS engine trimming after ET separation, in preparation for the OMS 1 burn, is accomplished externally to the Transition DAP, using the K-loaded values of OMSL_PITCH_YAW_CMD and OMSR_PITCH_YAW_CMD. This trim is initiated by activating the OMS TVC CMD SOP at the transition into MM 104.) TRNS_RECON will also set the value of TVC_LAW_P_Y_GAIN_FLAG (Table 4.4.4.1.3-2) as a function of the number of OMS engines commanded on.

- c. Set gains, deadbands, flags, etc. Table 4.4.4.1.3-3 is a list of TRNS_DAP interface parameters that are modified by TRNS_RECON. Table 4.4.4.1.3-2 is a list of parameters used within the TRNS_DAP whose values are modified by TRNS_RECON. The need for most of the latter are found in the module descriptions of Subsection 4.4.4.2.
- d. Clocking slow modules. TRNS_RECON will keep the clocks that are necessary to determine the proper time for calls to modules that are processed at a rate lower than 12.5 Hz. TRNS_RECON and the higher level scheduler must ensure that OMS_STEERING_TRANSITION is executed no later than 180 milliseconds after the IMU accelerometer read that generated the current value of DVB_SEC.
- e. Panel switch interfacing. TRNS_RECON will respond to moding requests from eight ORB DAP panel PBIs and will provide illumination to those PBIs indicating the moding in effect, except as noted in paragraph (2). The PBIs are DAP AUTO and DAP INTRL, used to specify automatic or manual moding, and a DISC RATE PBI and a PULSE PBI for each rotational axis, used to specify discrete rate or pulse rotation submodes of RCS-only operation. Inputs from these switches are momentary; that is, ON when a switch is presented, OFF when it is released.
 - (1) Automatic/manual moding. The logical expressions for response to the AUTO_REQUEST and MANUAL_REQUEST discretes are given in Table 4.4.4.1.3-3. RHC out-of-detent override to manual mode will be indicated by the PBIs.
 - (2) Discrete/pulse RCS rotation moding. The logical expressions for response to the DISC_REQUEST and PULSE_REQUEST discretes are given in the notes to Table 4.4.4.1.1-1 and in Table 4.4.4.1.3-3. RCS submodes in use during TVC, a guided RCS translation burn, or RHC soft-stop downmoding at any time, will not be indicated by the PBIs. During RCS-only operation, TRNS_RECON will not respond to or remember rotation submode change requests while the RHC is out of detent, and that fact will be indicated by the PBIs. RCS rotation submodes can be preset by PBI in either TVC mode regardless of RHC state, or guided RCS mode so long as the RHC is in detent. In this case, the PBIs indicate the mode that will be in effect during nonguided RCS-only operations.

Table 4.4.4.1.3-1. Control Law Function Module Initialization Conditions

Initialization Flag	Set flag on ENTRY into the specified mode or submode or when condition occurs
INIT_AUTO_MNVR	$[(RCS \cdot AUTO_MODE) = 0 \rightarrow 1] + (RCS \cdot PREBURN_MNVR \cdot ALFA_MNVR \cdot AUTO_MODE) + (NEW_QBI_CMD_FLAG \cdot MNVR_HOLD) + [SEP_MINUSZ_CMD = 0 \rightarrow 1] + (ALFA_MNVR = 1 \rightarrow 0 + ALFA_MNVR = 0 \rightarrow 1)$

4.4.4.2 Control Law Module.

Figure 4.4.4.2-1 is the major block diagram of the transition FC control law module. This module contains a number of function modules that execute the control laws. On any given pass, the configuration of the control law module (i.e., the effective interconnection and behavior of the function modules) is determined by inputs from the supervisory module TRNS_RECON.

Configuration control is implemented in four ways:

1. By executing the particular function modules necessary to perform a given task in the sequence required. This function is performed by TRNS_RECON and indicated in Figure 4.4.4.2-1 by switches whose logic was described in Subsection 4.4.4.1.
2. By passing initialization flags to the function modules which, in general, initialize pass-to-pass storage elements, such as filters, counters, and integrators.
3. By passing flags defining qualitative behavior of certain function modules. These flags perform low-level reconfigurations within the modules.
4. By passing parameters defining quantitative behavior of certain function modules. These parameters include gains and deadbands. (Certain other parameters are pad-loaded values that remain constant throughout the transition phases.)

The control law function modules are grouped into three categories: steering processor, RCS processor, and OMS processor. The general sequence of processing is (1) steering processor and (2) RCS, or RCS and OMS, processor.

A. Steering Processor. The steering processor converts a variety of input commands and data to forms acceptable by the RCS and OMS processors. It also generates an ET separation complete flag, and an attitude command used to generate an error display for manual steering in OMS TVC and guided manual RCS delta-V burns. In Figure 4.4.4.2-1, these modules are divided into the following types:

1. One manual RCS translation (TRANS_ACCEL_TRANSITION).

2. One automatic RCS translation and ET separation monitor (ET_SEP_PROCESSOR).
3. Three manual RCS rotation (ROT_ACCEL, ROT_DISC_TRANSITION, and ROT_PULSE_TRANSITION).
4. One automatic RCS rotation (AUTO_MNVR).
5. Two automatic OMS steering (OMS_STEERING_TRANSITION and GUIDANCE_COMPENSATION).
6. One manual OMS steering (MANUAL_TVC).
7. One RCS error determination and attitude data processing (RCS_ERRORS_TRANSITION).
8. One rate gyro output filter (RATE_FILTER).

The RCS translation modules generate commands for the jet selection module in the RCS processor. The manual RCS translation module processes the three vehicle axes together. The automatic RCS translation module processes only the vehicle Z-axis and, in addition, monitors the separation velocity in both manual and automatic translation modes, setting the SEP_COMPLETE flag when the desired separation velocity is achieved.

One of the RCS manual rotation modules, ROT_DISC_TRANSITION, generates rate commands for the RCS error determination module; the other two, ROT_ACCEL and ROT_PULSE_TRANSITION, drive the jet selection routine directly. Each RCS manual rotation module processes one axis at a time, enabling axis-by-axis downmoding from the discrete rate or pulse submode to the acceleration submode.

The automatic RCS rotation module, AUTO_MNVR, provides rate commands and attitude errors to the RCS error determination module to effect either an attitude hold or a maneuver to a commanded preburn attitude followed by an attitude hold.

The rotation modules ROT_DISC_TRANSITION and AUTO_MNVR supply the RCS processor with a FORCE_FIRE flag, which acts as a rate damping command. ROT_DISC_TRANSITION requests rate damping each time the RHC is deflected from detent, commanding a nonzero angular rate and, each time the RHC is returned to detent, commanding an attitude hold; TRNS_RECON makes the FORCE_FIRE request if the RHC was moved beyond soft stop and then back to detent. AUTO_MNVR commands FORCE_FIRE in all three axes when starting or ending a maneuver. This request causes the phase-plane switching logic in the RCS processor to initiate a firing such as to reduce the angular rate error. Hysteresis logic in the phase plane then continues the firing as needed to bring the rate error to an acceptably small magnitude, whereupon the phase-plane switching logic resumes normal limit cycle operation. The ROT_DISC_TRANSITION module must also initialize the RCS_ERRORS_TRANSITION module at three events in the discrete rate/attitude hold mode. This initialization sets the desired attitude equal to the present attitude; it is needed (1) when the mode is first entered, (2) when the RHC goes out of detent, and (3) when the RHC returns to detent.

The RATE_FILTER generates filtered rate gyro data for the RCS processor and is turned off during ET_SEP. The module RCS_ERRORS_TRANSITION accepts attitude errors from AUTO_MNVR, rate commands from the various steering command generators, and attitude and rate data from the external interface. From these, it derives attitude and rate errors for the RCS processor. After SEP_COMPLETE the rate data is filtered by RATE_FILTER.

The OMS steering modules generate body rate commands for the RCS processor (via RCS_ERRORS_TRANSITION) and for the OMS processor. The automatic steering module, OMS_STEERING_TRANSITION, commands a steering angle equal to the cross product of the desired and actual vehicle velocity vectors. The output of this module is scaled, filtered, and limited by GUIDANCE_COMPENSATION. The manual steering module, MANUAL_TVC, simply commands a rate proportional to the RHC deflection.

B. RCS Processor. The RCS processor consists of jet selection logic for rotation and translation, preceded by a phase-plane switching logic for rotation only, which processes attitude and angular rate errors to drive the vehicle into a limit cycle about the desired attitude and angular rate. In addition, the phase plane logic provides crossfeed signals to the OMS processor indicating the desired angular rate error and the RCS rotation commands. The jet selection logic produces the primary RCS processor output, the on-off commands to the RCS jets.

The command by which the phase plane drives the jet selection logic, ROT_JET_CMD, may be zeroed by TRNS_RECON to implement either of two kinds of free drift: axis-by-axis drift, discussed in part D below, and three-axis free drift for the initial part of the ET separation burn, discussed in paragraph 4.4.4.1.2.2.

C. OMS Processor. The OMS processor contains all the functions required for thrust vector control of the OMS engines. Because pitch and yaw may be controlled differently from roll, the TVC law function is split into two modules to prevent execution of unnecessary code, a mixer module performing the required roll/pitch command summations. Preburn trimming of the OMS engines is detailed in the functional description of the module TVC_LAW_PITCH_YAW.

D. RCS Manual Rotation Control Configuration. Anytime the discrete rate/ attitude hold or pulse rotation mode is available (i.e., during all manual RCS-only operations and, in the roll axis only, during a manual one-engine OMS burn), the acceleration mode is also available when the RHC is beyond the soft stop. To prevent fuel waste, the vehicle drifts freely when the RHC is returned to within soft stop but not to detent. When the RHC is returned to detent, or is on the opposite side of detent (having passed through detent undetected due to the finite RHC sampling rate) but not at the soft stop, the mode reverts to that previously in effect. Table 4.4.4.2-1 summarizes the control action and key signal states for three RHC deflection sequences: Sequence 1, in which the RHC remains within soft stop and the mode remains discrete rate/attitude hold; Sequence 2, in which the RHC remains within soft stop and the mode remains pulse; and Sequence 3, in which the RHC moves beyond soft stop and the accel/drift/discrete or accel/drift/pulse hysteresis is implemented. The signals described appear in Table 4.4.4.2-1.

E. RCS Translation Control Configuration. RCS translation is effected in one manual mode (through TRANS_ACCEL_TRANSITION) and one special-purpose automatic mode. All translation modes supply an RCS jet command to the RCS processor. The manual acceleration mode is always available to the crew and generates a jet command for a given axis, as long as the THC is out of detent in that axis, to accelerate the vehicle along that axis in a direction corresponding to the sense of the THC deflection. TRNS_RECON and ET_SEP_PROCESSOR implement the automatic -Z maneuver mode, which is active only during ET separation. In this mode, TRNS_RECON generates a -Z jet command until the vehicle has accelerated in -Z to the desired separation velocity, at which time ET_SEP_PROCESSOR terminates the command and sets the flag SEP_COMPLETE. Any use of the THC while this mode is in progress downmodes translation control to manual acceleration mode; however, ET_SEP_PROCESSOR continues to monitor separation velocity until the desired value is reached.

F. TVC Control Configuration. In TVC operation, the OMS and RCS processors are driven by three-axis commands from the steering processor. For axes in which the OMS processor has control capability (roll, pitch, and yaw in a two-engine burn; pitch and yaw in a one-engine burn), it has the primary control responsibility; and the RCS processor operates as a wraparound controller, exercising RCS control only if the TVC control authority is inadequate, as evidenced by excessive attitude or angular rate errors. In a one-engine burn, roll is controlled exclusively by the RCS processor, operating with the same attitude and angular rate error tolerances as in the two-engine case.

The steering processor provides the drive signals to the OMS and RCS processors. For the OMS processor, these drive signals are body rate commands. For the RCS processor, they are either attitude error and angular rate error signals derived from body rate commands, or RCS jet commands. In automatic TVC mode, OMS_STEERING_TRANSITION and GUIDANCE_COMPENSATION provide the body rate commands to the OMS processor, and RCS_ERRORS_TRANSITION generates error signals based on these commands for the RCS processor.

In manual TVC mode, MANUAL_TVC provides the body rate commands to the OMS processor, and the RCS processor is driven by signals that are a function of the number of OMS engines active, the RHC deflection (within or beyond soft stop), and (in the one-engine case) the particular body axis. In a two-engine burn, with the RHC within soft stop, RCS_ERRORS_TRANSITION supplies error signals to the RCS processor based on the rate commands from MANUAL_TVC. If the RHC is deflected beyond soft stop in any axis, that axis is driven by RCS jet commands from ROT_ACCEL. In a one-engine burn, pitch and yaw control operate identically to the two-engine case for both RHC conditions. Roll control in the one-engine case is by ROT_DISC_TRANSITION via RCS_ERRORS_TRANSITION when the RHC is within soft stop and by RCS jet command from ROT_ACCEL when the RHC is beyond soft stop. The acceleration/drift/discrete hysteresis described in Paragraph D applies to roll control in the one-engine case.

Table 4.4.4.2-2 summarizes the TVC control configurations. Control inputs to the OMS and RCS processors are indicated for all relevant combinations of mode, number of engines, RHC deflection, and axis.

G. Attitude Command Control Configuration. The steering processor selects either of two attitude quaternions for the automatic maneuver module, AUTO_MNVR, which maneuvers to and/or holds the commanded attitude if in RCS automatic mode. It also supplies either of two quaternions to the A/E ATT PROC, which generates an attitude error signal on the ADI. In Major Mode 103, the quaternion sent to A/E ATT PROC is the same as that selected for AUTO_MNVR. After entering Major Mode 104, the quaternion shipped to A/E ATT PROC is always Q_B_I_CMD. The rate at which Q_B_I_CMD is supplied to the DAP and sent on to A/E ATT PROC depends on the circumstances. For a preburn maneuver, Q_B_I_CMD is supplied once. During a TVC or guided RCS burn, the commanded attitude, Q_B_I_CMD, is supplied at 1.04 Hz. The resulting display can be used by the crew as visual input for manual attitude control using the RCS and/or OMS, and to monitor attitude control during an automatic OMS burn or an automatic RCS maneuver or hold.

The quaternion received by AUTO_MNVR depends on whether it is desired to maneuver to and/or hold a commanded attitude or to hold the current attitude. AUTO_MNVR receives the commanded attitude Q_B_I_CMD if PREBURN_MNVR goes high during RCS automatic mode, or if ALFA_MNVR flag is set ON, and during a guided RCS burn. (It also “receives” Q_B_I_CMD, but is not executed, during a TVC burn.) A snapshot value of the current attitude, Q_B_I, is provided to AUTO_MNVR at (1) the end of an OMS or guided RCS burn, (2) ET separation, (3) the start of the insertion and deorbit phases, (4) change from RCS automatic to RCS manual mode or, vice versa, if a guided RCS burn is not in progress,

(5) if the commanded attitude is changed (different from the target attitude) while in the course of an automatic PREBURN maneuver, and (6) at the end of the ALFA_BETA maneuver.

H. Function Module Descriptions. The control law function modules are described in Subsections 4.4.4.2.1 through 4.4.4.2.3. Within these subsections, the modules are ordered alphanumerically by name. The groupings are as follows:

Section	Subject
4.4.4.2.1	Steering processor modules
4.4.4.2.2	RCS processor modules
4.4.4.2.3	OMS processor modules

Table 4.4.4.2-1. RCS Manual Rotation Moding and Signal Flow

FORCE_FIRE, RHC Position and Relevant Conditions	Control Action	INIT_RCS_ ERRORS	ROT_JET_CMD
Sequence 1: RHC remains within soft stop for discrete rate/ attitude hold mode.			
In detent	Hold attitude	OFF	As required
Out of detent, first pass	Damp to rate	ON	± 1
Out of detent, rate not achieved	Damp to rate	OFF	± 1
*Out of detent, rate achieved	Maintain rate	OFF	As required
Back in detent, first pass	Damp to zero	ON	± 1
Back in detent, rate not zeroed	Damp to zero	OFF	± 1
Back in detent, rate zeroed	Hold attitude	OFF	As required
Sequence 2: RHC remains within soft stop for pulse mode.			
In detent	Free drift	Don't care	0
Out of detent, rate change not achieved	Acceleration	Don't care	± 1
Out of detent, rate change achieved	Free drift	Don't care	0
In detent	Free drift	Don't care	0
Sequence 3: RHC moves beyond soft stop for either mode.			
In detent	_____	See above	_____
Out of detent, all conditions	_____	See above	_____
Beyond soft stop	Acceleration	Don't care	± 1
Within soft stop, out of detent	Free drift	Don't care	0
Back in detent, all conditions	_____	See above	_____
*This step is skipped if the RHC is returned to detent before the RCS can achieve the discrete rate.

4.4.4.2.1 Steering Processor

4.4.4.2.1.1 AUTO_MNVR.

A. Function. This module generates control signals to effect an attitude hold or maneuver to a commanded attitude followed by an attitude hold. The module initiates in a maneuver or hold mode as a function of the magnitude of the difference between the actual vehicle attitude and the target attitude. If the initial mode is maneuver, the module computes the time needed to complete the maneuver. The time to maneuver completion is then decremented via an open loop cycle counter. The mode is changed to hold at the end of this time. The time is also sent to XXXXX MNVR DIP for further processing and then displayed via XXXXX MNVR YYYYYY. The FORCE_FIRE flags are used to ensure prompt vehicle response to transitions between these modes. The detailed block diagram for the module AUTO_MNVR is presented in Figures 4.4.4.2.1.1–1 and 4.4.4.2.1.1–2.

B. Processing Requirements. The module AUTO_MNVR shall be called on the first pass of the TRANS_DAP and processed at 1.04 Hz.

C. Interface Requirements. The interface requirements for the module AUTO_MNVR are shown in Table 4.4.4.2.1.1–1.

D. K-Loads/Constants. The K-loads/constants for the module AUTO_MNVR are shown in Table 4.4.4.2.1.1–2.

E. Initialization Requirements. The initialization requirements for the module AUTO_MNVR are included in Figure 4.4.4.2.1.1–1.

Table 4.4.4.2.1.1-1. AUTO_MNVR Interface Requirements

Name	Description	Source or Destination	Type	Range	Unit	Sample Rate(Hz)
Inputs						
INIT_AUTO_MNVR	Module initialization flag (1=init)	TRNS_RECON	B	0,1	none	1.04
Q_B_I	Vehicle attitude with respect to reference attitude, given as the M50-to-body quaternion	ASCENT/ENTRY ATT PROC	Struct:S; V(3)S	0 to 1; -1 to 1	none	1.04
Q_B_I_CMD_DESIRED	Commanded vehicle attitude with respect to reference attitude, given as the M50-to-body quaternion	ASCENT/ENTRY ATT PROC, AS MNVR DIP, DEORB MNVR DIP, ORB INS GUID, or DEORB GUID (via unity gain), ALFA_BETA_MNVR	Struct:S; V(3)S	0 to 1; -1 to 1	none	1.04
TERM_AUTO	Flag indicating that guidance has updated the desired attitude during a preburn maneuver	TRNS_RECON	B	0,1	none	1.04
MNVR_RATE	Maneuver Rate About Eigen Axis	TRNS_RECON	S	.5 to 5.0	deg/sec	1.04
Outputs						
ATTITUDE_ERROR	Body angle error	RCS_ERRORS_TRANSITION	V(3)S	-360 to 360	deg	1.04
FORCE_FIRE	Rate damping initiation flag by axis (1=damp rate)	PHASE_PLANE_TRANSITION	B(3)	0,1 for each bit	none	1.04
OMEGA_C_BODY	Desired body angular rate	RCS_ERRORS_TRANSITION	V(3)S	-5 to 5	deg /s	1.04
MNVR_CMPL_TIME_TGO	Preburn maneuver time to go	AS MNVR DIP, DEORB MNVR DIP	S		s	1.04

4.4.4.2.1.2 ET_SEP_PROCESSOR.

A. Function. This module monitors translation along the vehicle –Z axis until a desired velocity increment is achieved. The module operates closed loop by using the measured vehicle velocity increments. When the module determines that the desired velocity increment has been achieved, it zeroes the translation command and sets a flag. The detailed block diagram for the module ET_SEP_PROCESSOR is presented in Figure 4.4.4.2.1.2–1.

B. Processing Requirements. The module ET_SEP_PROCESSOR is processed at 1.04 Hz.

C. Interface Requirements. The interface requirements for the module ET_SEP_PROCESSOR are shown in Table 4.4.4.2.1.2–1.

D. I-loads. I-loads for the module ET_SEP_PROCESSOR are shown in Table 4.4.4.2.1.2–2.

E. Initialization Requirements. The initialization requirements for the module ET_SEP_PROCESSOR are shown in Table 4.4.4.2.1.2–3.

4.4.4.2.1.4 MANUAL_TVC.

A. Function. This module provides commands to generate a three-axis vehicle angular rate during a TVC burn. The generated rate corresponds in sense and magnitude to the RHC deflection and is constrained to a limiting value. The detailed block diagram for MANUAL_TVC is presented in Figure 4.4.4.2.1.4-1.

B. Processing Rate. MANUAL_TVC is processed at 12.5 Hz.

C. Interface Requirements. The interface requirements for MANUAL_TVC are shown in Table 4.4.4.2.1.4-1.

D. K-loads. The K-loads for MANUAL_TVC are shown in Table 4.4.4.2.1.4-2.

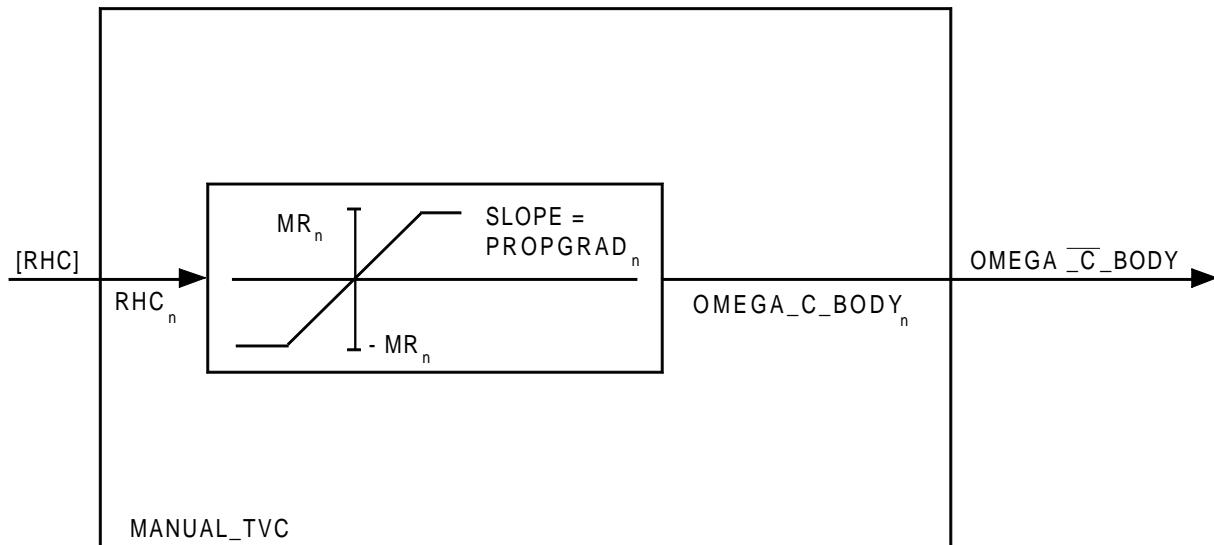

E. Initialization Requirements. There are no initialization requirements for MANUAL_TVC.

4.4.4.2.1.5 OMS_STEERING_TRANSITION.

A. Function. This module commands a vehicle steering angle equal to the vector cross product of the commanded thrust direction and the sensed vehicle velocity change. If the sensed velocity falls below a threshold value, the module holds its output at the previous value until passage of a time delay (measured in cycles at the module processing rate); the output is then set to zero. However, anytime the sensed velocity change equals or exceeds the threshold value, normal processing is resumed and the delay timer is reset. The detailed block diagram for OMS_STEERING_TRANSITION is presented in Figure 4.4.4.2.1.5-1.

B. Processing Rate. OMS_STEERING_TRANSITION is processed at 1.04 Hz.

C. Interface Requirements. The interface requirements for OMS_STEERING_TRANSITION are presented in Table 4.4.4.2.1.5-1.

D. K-Loads/Constants. The K-loads/constants for OMS_STEERING_TRANSITION are presented in Table 4.4.4.2.1.5-2.

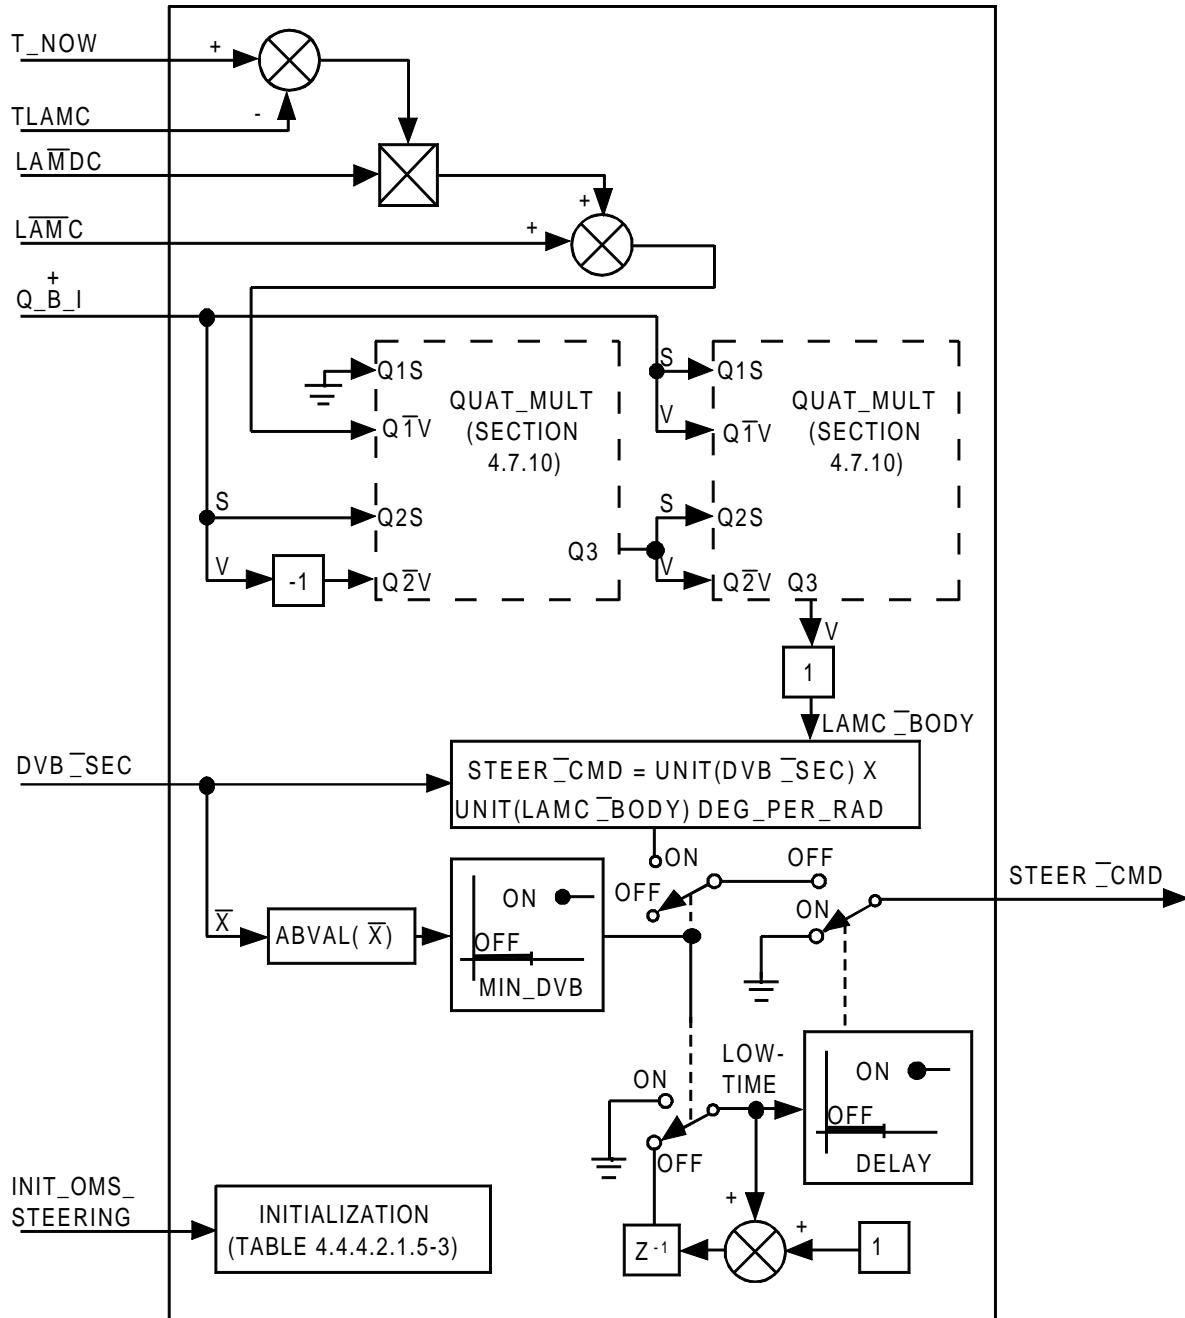

E. Initialization Requirements. The initialization requirements for OMS_STEERING_TRANSITION are presented in Table 4.4.4.2.1.5-3.

FIGURE 4.4.4.2.1.5-1. OMS_STEERING_TRANSITION

4.4.4.2.1.6 RCS_ERRORS_TRANSITION.

A. Function. This module obtains the vehicle attitude error and angular rate error based upon an angular rate command from steering processor modules, an attitude error signal from AUTO_MNVR, and vehicle measurement data. It first forms the desired attitude increment by multiplying the desired angular rate by the time step. Then the attitude error is updated by the difference between the desired and measured attitude increments. The angular rate error is the difference between the desired and measured rates.

The initialization flag for this module sets a given component of the attitude error to zero. This action is typically invoked upon assumption or resumption of control of a given body axis by a steering processor module. In the particular case of the manual discrete rate command/attitude hold submode, the initialization flag is set (in addition to entry into the submode) when the RHC is moved into or out of detent. The detailed block diagram for the module RCS_ERRORS_TRANSITION is presented in Figure 4.4.4.2.1.6-1.

B. Processing Requirements. The module RCS_ERRORS_TRANSITION is processed at 12.5 Hz.

C. Interface Requirements. The interface requirements for the module RCS_ERRORS_TRANSITION are shown in Table 4.4.4.2.1.6-1.

D. Constants. The constants for the module RCS_ERRORS_TRANSITION are shown in Table 4.4.4.2.1.6-2.

E. Initialization Requirements. The initialization requirements for the module RCS_ERRORS_TRANSITION are shown in Table 4.4.4.2.1.6-3.

Table 4.4.4.2.1.6-1. RCS_ERRORS_TRANSITION Interface Requirements

Name	Description	Source or Destination	Type	Range	Unit	Sample Rate (Hz)
Inputs						
ATTITUDE_ERROR	Body angle error	AUTO_MNVR	V(3)S	-360 to 360	deg	12.5

4.4.4.2.1.7 ROT_DISC_TRANSITION.

A. Function. For each vehicle axis that is in the manual discrete rate rotation submode, this module provides commands to generate a predetermined vehicle angular rate about that axis while the RHC is out of detent in that axis. The sense of the angular rate corresponds to the sense of the RHC deflection. When the RHC is in detent, an attitude hold is performed in the affected axis; the vehicle maintains the attitude it had at the instant the RHC went into detent. The detailed block diagram for the module ROT_DISC_TRANSITION is presented in Figure 4.4.4.2.1.7-1.

B. Processing Requirements. The module ROT_DISC_TRANSITION is processed at 12.5 Hz per axis.

C. Interface Requirements. The interface requirements for the module ROT_DISC_TRANSITION are shown in Table 4.4.4.2.1.7-1.

D. K-loads. The K-loads for the module ROT_DISC_TRANSITION are shown in Table 4.4.4.2.1.7-2.

E. Initialization Requirements. The initialization requirements for the module ROT_DISC_TRANSITION are included in Figure 4.4.4.2.1.7-1.

Table 4.4.4.2.1.7-1. ROT_DISC_TRANSITION Interface Requirements

Name	Description	Source or Destination	Type	Range	Unit	Rate (Hz)

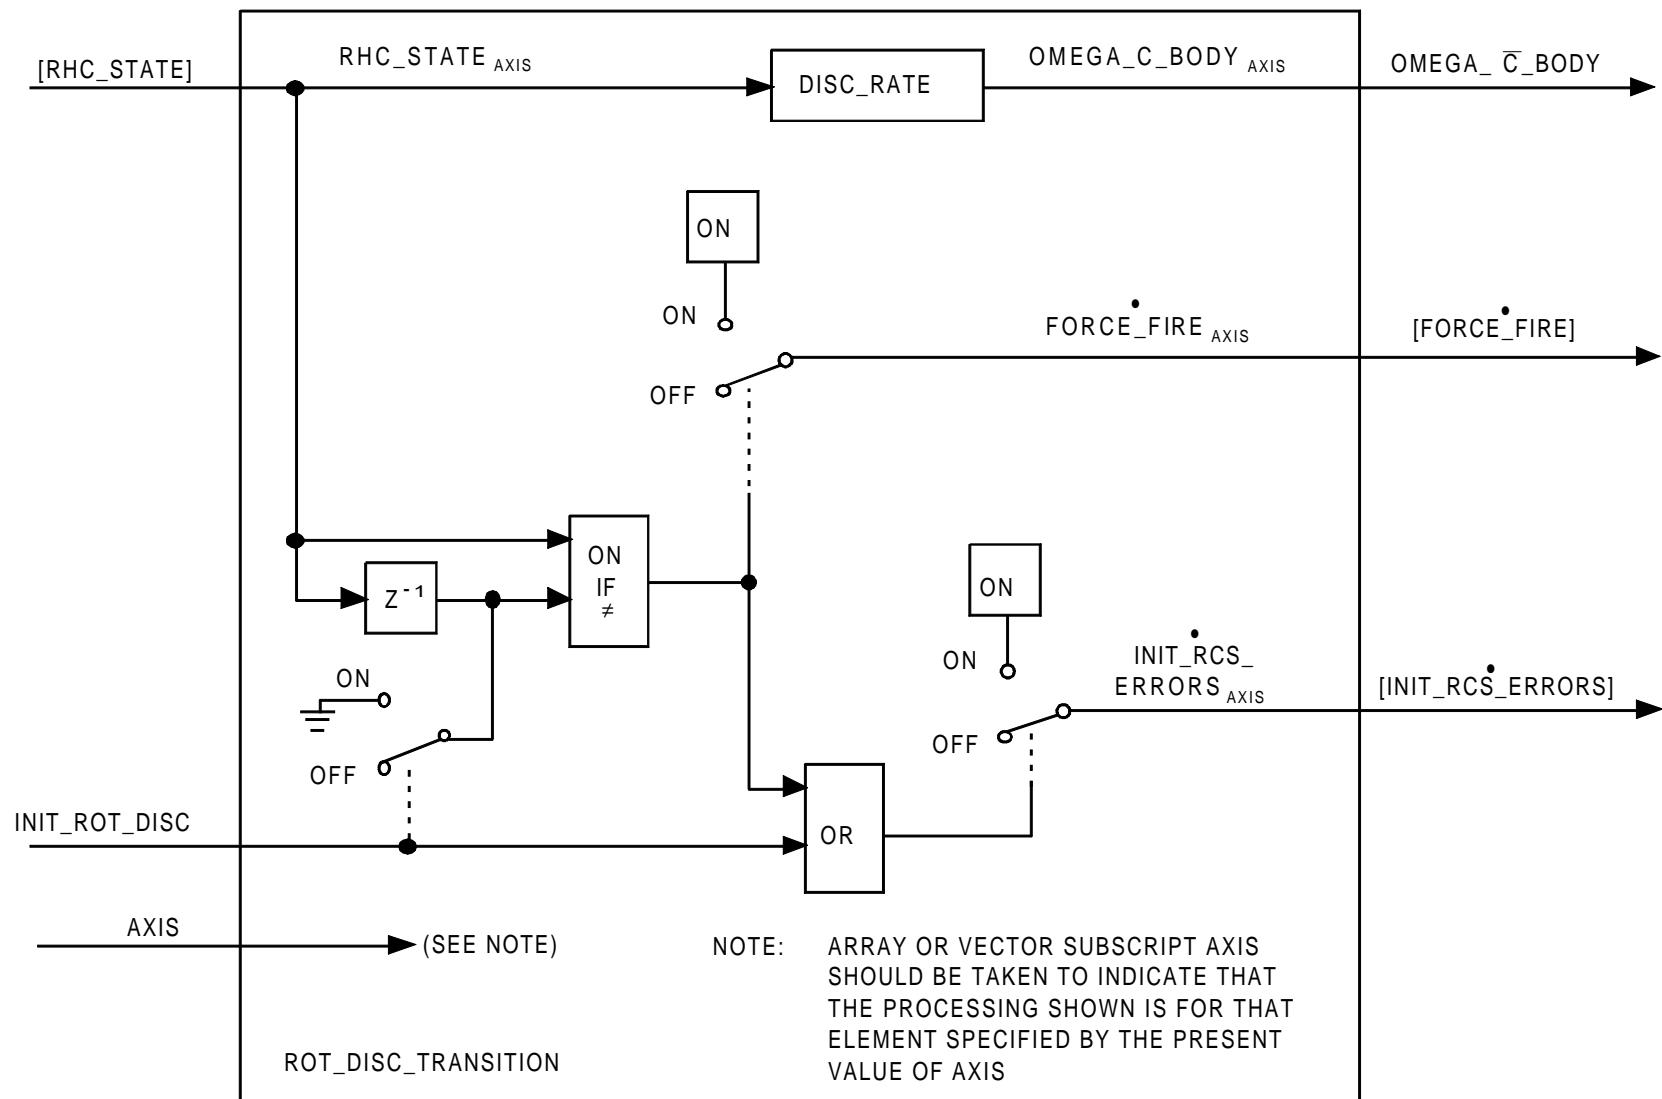

FIGURE 4.4.4.2.1.7-1. ROT_DISC_TRANSITION

4.4.4.2.1.8 ROT_PULSE_TRANSITION.

A. Function. For each vehicle axis that is in the manual pulse rotation submode, this module provides a command to generate a predetermined vehicle angular rate increment about that axis for each time the RHC is moved out of detent in that axis. The sense of the angular rate increment corresponds to the sense of the RHC deflection. When the sum of all commanded rate increments about a given axis has been attained, vehicle rotation about that axis is in free drift, regardless of whether the RHC is in detent or out of detent in that axis. The module operates open loop by determining how many passes the RCS jets must fire to implement each commanded rate increment and maintaining a jet command of the correct sign for the total number of passes needed.

B. Block Diagram. The block diagram for ROT_PULSE_TRANSITION is shown in Figure 4.4.4.2.1.8-1.

C. Processing Rate. The module ROT_PULSE_TRANSITION is processed at 12.5 Hz/axis.

D. Interface Requirements. The interface requirements for the module ROT_PULSE_TRANSITION are shown in Table 4.4.4.2.1.8-1.

E. K-Loads/Constants. The K-loads/constants for the module ROT_PULSE_TRANSITION are shown in Table 4.4.4.2.1.8-2.

F. Initialization Requirements. The initialization requirements for the module ROT_PULSE_TRANSITION are shown in Table 4.4.4.2.1.8-3.

4.4.4.2.1.10 ALFA_BETA_MNVR

A. Function. This task calculates a desired quaternion in inertial frame to keep the vehicle within the targeted angle of attack and side slip angle during mated coast for both nominal and TAL trajectories and MM-104 for TAL trajectories.

Detailed Requirements

- 1) The M50-to-commanded body quaternion is computed in the following manner.
 - a) The quaternion $Q_{M50_VR}^+$ is found by using the function RV_TO_QLVLH. In this function, the coordinate system is defined by setting the \bar{Z} axis equal to the unit negative of the first input vector, the \bar{Y} axis equal to the unit vector of the second input vector crossed into the first input vector, and the \bar{X} axis equal to $\bar{Y} \times \bar{Z}$. The determination of a heads up or heads down attitude is done using body roll attitude euler angle, where heads up is defined as the absolute value of the body roll attitude euler angle $< 90^\circ$, and the heads down is the absolute value of the body roll attitude euler angle $\geq 90^\circ$. The quaternion representing the transformation from this coordinate system, called the VR coordinate system to the M50 coordinate system is computed as follows for heads up and heads down.

Heads up: $Q_{M50_VR}^+ = RV_TO_QLVLH(V_{\bar{R}\text{HO}}, -R_{\bar{A}\text{VGG}})$, Note negative on R_AVGG.

Heads down: $Q_{M50_VR}^+ = RV_TO_QLVLH(V_{\bar{R}\text{HO}}, R_{\bar{A}\text{VGG}})$

- b) Construct the angle of rotation from the VR frame to the desired angle of attack, ALPHAQ.

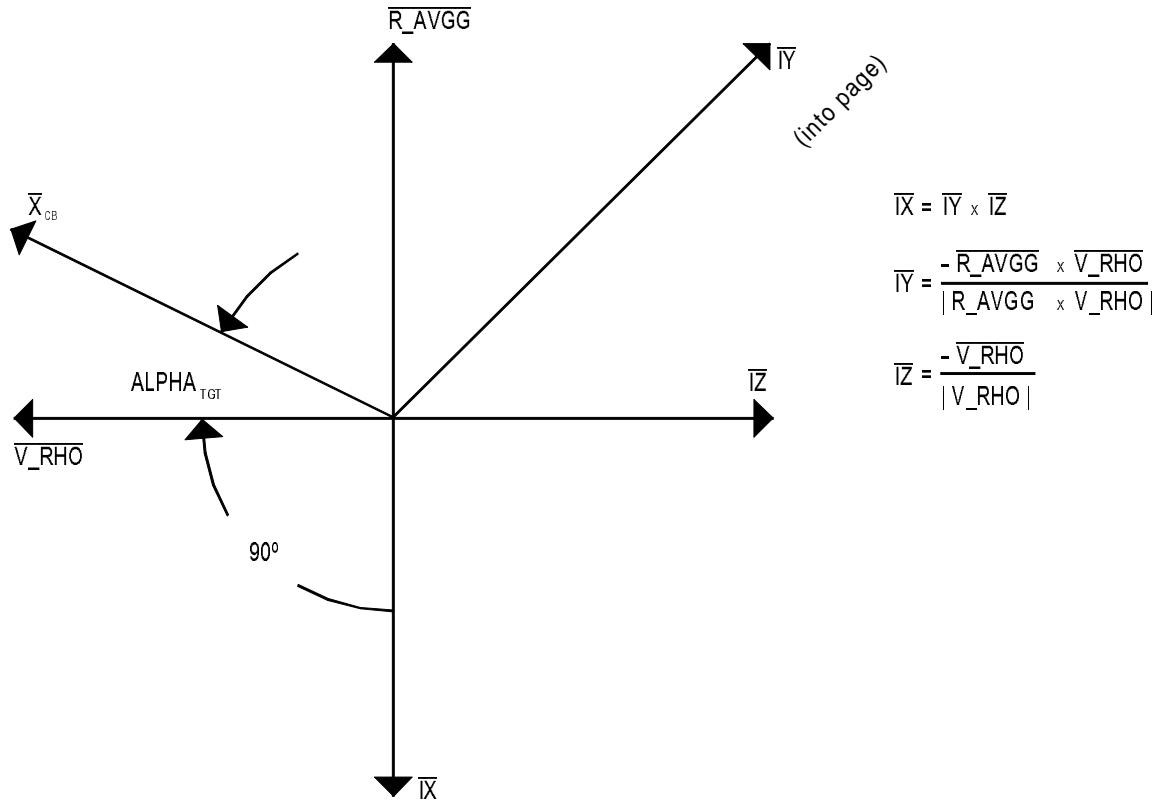

$$Q_{CB_VR}^+ = QUAT_CALC(ALPHAQ, U\bar{Y}), \text{ where } U\bar{Y} = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}, \text{ the right wing unit vector.}$$

- c) Construct the M50-to-commanded body quaternion to command wings level, zero sideslip, and the computed angle of attack. The M50-to-commanded body quaternion is formed by multiplying the rotation quaternion ($Q_{CB_VR}^+$) by the conjugate of the VR-to-M50 quaternion ($Q_{M50_VR}^+$).

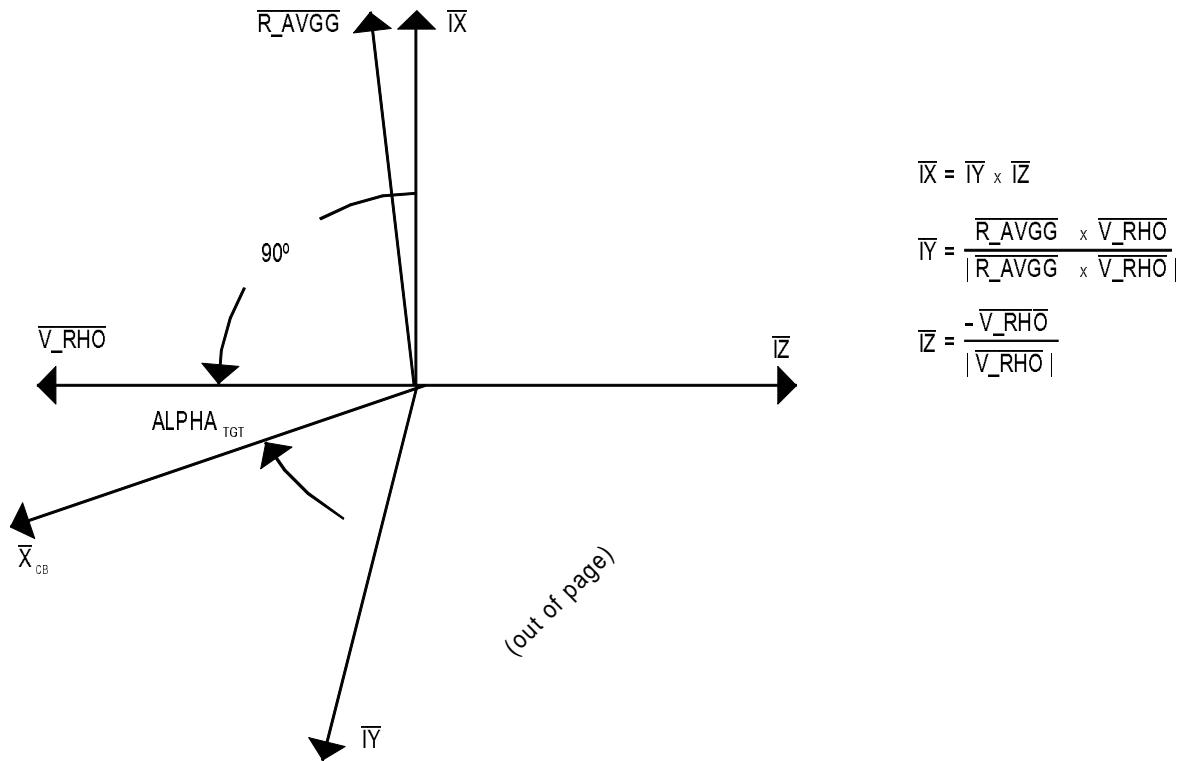

$$Q_{B_I_CMD}^+ = QUAT_MULT(Q_{CB_VR}^+, Q_{VR_M50}^+)$$

- d) ALPHAQ is set to an I-load target $+90^\circ$. The rationale for the 90° bias on ALPHAQ is that the bias is needed to align the x-axis of this LVLH coordinate system with the velocity vector.

For the heads-up case, the z-axis is pointing opposite to the velocity vector, the y-axis is pointing to the right wing, and the coordinate system is completed with the x-axis pointing down opposite to the general direction of the position vector.

For the heads-down case, the z-axis is pointing opposite to the velocity vector, the y-axis is pointing to the right wing (since it is heads-down, this is to the left of the velocity vector), and the coordinate system is completed with the x-axis pointing in the general direction of the position vector.

B. Processing Requirements. The ALFA_BETA_MNVR task is performed once each time the task is called.

C. Interface Requirements. The interface requirements for ALFA_BETA_MNVR are shown in Table 4.4.4.2.1.10-1

D. Constants. Unit vector U=0,1,0

E. Initialization Requirements. There are no initialization requirements.

Table 4.4.4.2.1.10-1. ALFA_BETA_MNVR Interface Requirements						
Name	Description	Source/Destination	Type	Range	Unit	Sample Rate (Hz)
Inputs						
ALPHAQ	Desired alpha target	TRNS_RECON	S		deg	12.5

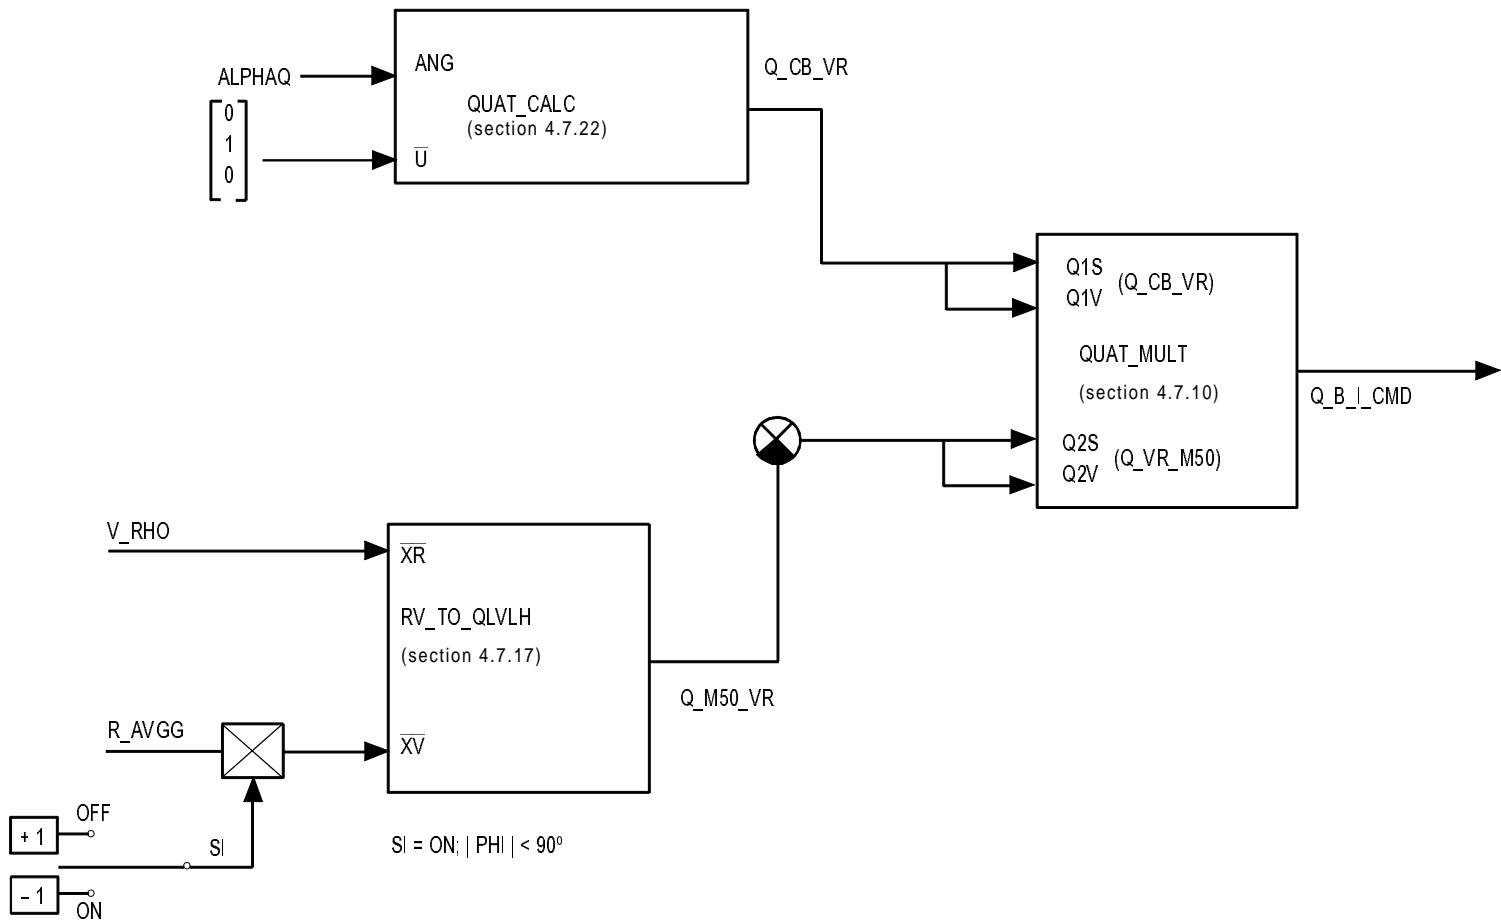

FIGURE 4.4.4.2.1.10-1. ALFA_BETA_MNVR

4.4.4.2.2 RCS Processor.

4.4.4.2.2.1 JET_SELECT_TRANSITION.

A. Function. This module generates jet firing commands required to implement commanded translations and rotations. The transition jet select contains logic enabling selection of primary jets only. The algorithm takes into account jet failures, ET separation, RCS propellant crossfeed valve position, and tank constraints. Logic is included to permit propellant dumping through forward RCS jets for vehicle mass and c.g. control. Translation commands are ignored during dumping. Jet selection is according to a table look-up scheme, described in this subsection under paragraph F and in Tables 4.4.4.2.2.1–1 through 4.4.4.2.2.1–4. The detailed block diagram for the module JET_SELECT_TRANSITION is presented in Figures 4.4.4.2.2.1-1 through 4.4.4.2.2.1-12.

B. Processing Requirements. The module JET_SELECT_TRANSITION is processed at 12.5 Hz.

C. Interface Requirements. The interface requirements for the module JET_SELECT_TRANSITION are shown in Table 4.4.4.2.2.1–5.

D. Constants. There are no constants for JET_SELECT_TRANSITION.

E. Initialization Requirements. There are no initialization requirements for JET_SELECT_TRANSITION.

F. Detailed Function. This paragraph explains the table look-up logic and provides supporting comments for some of the block diagrams. Also included are data on RCS jet configuration.

The tables are divided into three sections (Tables 4.4.4.2.2.1–1 through 4.4.4.2.2.1–3). The first section provides the logic for the 19 jets that fire into the Z-axis: Part A for through ET separation, -Z translation, no -X translation, and either crossfeed closed or no +X translation; Part B for through ET separation, -Z translation, and -X translation; Part C for through ET separation, -Z translation, +X translation, and crossfeed open; Part D for after ET separation and -Z translation; Part E for all other cases (i.e., no -Z translation). These jets divide into seven directional jet clusters; namely, Groups 4, 5, 6, 11, 12, 13, and 14. The second section provides logic for the 12 jets that fire into the Y-axis. These jets divide into four directional jet clusters; namely, Groups 2, 3, 9, and 10. The third section provides logic for the seven jets that fire into the X-axis. These jets divide into three directional jet clusters; namely, Groups 1, 7, and 8 (see Figure 4.4.4.2.2.1–13 for RCS jet locations and plume directions).

Each page of the table look-up logic has three main divisions. The leftmost division provides the command to be responded to. The middle division lists all relevant failure combinations (through one failure with translation and two failures with no translation). The right-most division specifies how many jets must be commanded to fire in each directional group under the conditions specified. In the middle division, the first row of each command configuration is always the no-failure case. The rows that follow list a group number for the location of a failed jet (e.g., 9 means a jet has failed in Group 9). In the event that more failures occur than are covered by the tables, all the unfailed jets of those jets specified by the tables should be used.

The table look-up logic determines (for nominal and failure conditions) the total number by group of RCS jets to be fired. This information, in conjunction with the availability of jets (HFAIL_JSL), is used to determine which jets within a particular RCS jet group should be fired (NEW_JONLST_JSL). This selection is performed by choosing the required number of jets for each group among the unfailed jets

within that group and with the highest priority within that group. Table 4.4.4.2.2.1–6 gives the jet group and jet priority associated with each element of NEW_JONLST_JSL and HFAIL_JSL. Note that no particular RCS jet is associated with each element of either parameter.

As a limited example, suppose the second– and third–priority jets of Group 9 were not available for firing $HFAIL_{JSL_{19 \text{ to } 22}} = (0, 1, 1, 0)$ and that the table look–up logic required that two jets in Group 9 be fired, then $NEW_{JONLST}_{JSL_{19 \text{ to } 22}}$ would be set equal to $(1, 0, 0, 1)$.

The principle behind the table look–up scheme is that all jets that fire in the Z–axis can give Z–translation and/or roll rotation and/or pitch rotation control. These 19 jets are considered independent of other axes, however. All jets fired in the Y–axis are considered to give Y–translation and/ or yaw rotation only. All jets fired in the X–axis are considered to give X–translation control only. Interactions between axes are handled by phaseplane feedback and/or closed–loop feedback.

The priority of a particular RCS jet within its group is a mission–dependent and/or a crew–dependent function. Thus a mechanism is needed to identify which particular jet is associated with a particular in–group priority. This mechanism is the parameter JET_MAP. For JET_MAP to work properly, the input and output interfaces (AVAILABLE_JET_FWD, AVAILABLE_JET_AFT, NEW_JONLST_FWD, and NEW_JONLST_AFT) must be aligned identically, i.e., each respective element must refer to the same RCS jet. JET_MAP is an array of input/output interface array element numbers arranged by ascending group number and in order of descending priority (see Table 4.4.4.2.2.1–4 for arrangement). JET_MAP is used in the following equations (Figures 4.4.4.2.2.1–1 and –11):

I=1 TO 14

$$HFAIL_{JSL_I} = \overline{AVAILABLE_{JET_FWD}}_{JET_MAP_I}$$

I=15 TO 38

$$HFAIL_{JSL_I} = \overline{AVAILABLE_{JET_AFT}}_{JET_MAP_I}$$

I=1 TO 14

$$NEW_{JONLST}_{FWD_{JET_MAP_I}} = NEW_{JONLST}_{JSL_I}$$

I=15 TO 38

$$NEW_{JONLST}_{AFT_{JET_MAP_I}} = NEW_{JONLST}_{JSL_I}$$

As a limited example note that Group 1 Jets F1F, F2F, and F3F availability and commands are represented by Elements 1, 5, and 13, respectively, on the input/output interface for the forward jets. Suppose that the preferred firing order within Group 1 is F2F, F3F, F1F, then

$$JET_MAP_{1 \text{ to } 3} = (5, 13, 1), \text{ and}$$

$$HFAIL_{JSL_1} = \overline{AVAILABLE_{JET_FWD_5}}$$

$$HFAIL_{JSL_2} = \overline{AVAILABLE_{JET_FWD_{13}}}$$

$$HFAIL_{JSL_3} = \overline{AVAILABLE_{JET_FWD_1}}$$

$$NEW_{JONLST}_{FWD_5} = NEW_{JONLST}_{JSL_1}$$

$$NEW_{JONLST}_{FWD_{13}} = NEW_{JONLST}_{JSL_2}$$

$$NEW_{JONLST}_{FWD_1} = NEW_{JONLST}_{JSL_3}$$

Table 4.4.4.2.2.1-1 is in five parts. Parts A through C are to be accessed only if there is a -Z translation and SEP_COMPLETE = OFF. Part A is for the case with CROSSFEED_OPEN = OFF or no +X translation command combined with no -X translation command. Part B is for the case with -X translation command. Part C is for the case with CROSSFEED_OPEN = ON combined with +X translation command. Part D is to be accessed only if there is -Z translation command and SEP_COMPLETE = ON. Part E is to be accessed only if there is no -Z translation command. The following inputs signify the following commands:

ACOM:	ACOM _{1 to 4}	Ignore
	ACOM ₆	ON = Z translation required OFF = No Z translation required
	ACOM ₅	ON = Minus sign for Z translation OFF = Plus sign for Z translation
	ACOM ₈	ON = Roll rotation required OFF = No roll rotation required
	ACOM ₇	ON = Minus sign for roll rotation OFF = Plus sign for roll rotation
	ACOM ₁₀	ON = Pitch rotation required OFF = No pitch rotation required
	ACOM ₉	ON = Minus sign for pitch rotation OFF = Plus sign for pitch rotation
	ACOM _{11 to 12}	Ignore

In Table 4.4.4.2.2.1–2, the following inputs signify the following commands:

ACOM:	ACOM _{1 to 2}	Ignore
	ACOM ₄	ON = Y translation required
		OFF = No Y translation required
	ACOM ₃	ON = Minus sign for Y translation
		OFF = Plus sign for Y translation
	ACOM _{5 to 10}	Ignore
	ACOM ₁₂	ON = Yaw rotation required
		OFF = No yaw rotation required
	ACOM ₁₁	ON = Minus sign for yaw rotation
		OFF = Plus sign for yaw rotation

In Table 4.4.4.2.2.1–3, the following inputs signify the following commands:

ACOM:	ACOM ₂	ON = X translation required
		OFF = No X translation required
	ACOM ₁	ON = Minus sign for X translation
		OFF = Plus sign for X translation
	ACOM _{3 to 12}	Ignore

RCS tank constraints are met by either modifying the translation and rotation commands (represented by the ACOM array) prior to the table look-up or by modifying the jet commands (represented by the NEW_JONLST_JSL array) after the table look-up. The requirements are written in this way so that when the tank constraints are removed, the basic look-up tables will not change. Thus, even though simultaneous X and Z translations are prevented by the single-axis translation logic, the look-up tables contain entries for simultaneous X and Z translation.

The purpose of the single axis translation logic (Figure 4.4.4.2.2.1–3A) is to prevent jets from being commanded simultaneously in the X and Z translation axes in the event of simultaneous translation commands. The result is a reduced likelihood of exceeding the number of simultaneous jet firings that permit helium gas ingestion into the RCS propellant tank lower compartment. In the event that both the X and Z translation commands are generated, priorities for response are used. The priorities are Z axis first and X axis second through ET separation and X axis first and Z axis second after ET separation.

The purpose of the Y translation default (Figure 4.4.4.2.2.1–4) condition is to ensure that no Y translation is attempted when both forward Y-firing jets on the same side of the vehicle nose have failed. Without so doing, translation could only be accomplished with excessive yaw rotation.

The purpose of the aft Z-rate default (Figure 4.4.4.2.2.1–5) condition is to meet post-ET separation tank constraints with an open RCS propellant crossfeed valve or an open RCS/OMS interconnect valve. After ET separation, only five aft jets can fire simultaneously with open crossfeed. If +X translation and –Z translation occur simultaneously, –Z translation must be degraded to keep within the five-jet limit.

The purpose of the X-rate default (Figure 4.4.4.2.2.1–6) condition is to meet tank constraints. After ET separation with open crossfeed, a limit of five aft jets applies. Between degrading –Z translation to two aft jets and +X translation to two aft jets, the constraint can be met. The +X translation is thus degraded if any Z jets are used. Through ET separation, two problem areas occur. With open crossfeed, a seven-aft-jet limit applies. If –Z translation and +X translation occur simultaneously, both must be degraded to stay within constraints. The +X change is reflected in the block diagram, the –Z change in the tables (it is reduced from high –Z to near nominal). With closed crossfeed, a constraint of five jets per aft pod must be met. This can be exceeded when –Z and +X translation occur simultaneously with Y translation or yaw rotation. By degrading +X, the constraint is met.

The aft pitch default (Figure 4.4.4.2.2.1–7) prevents forward pitch jets from being utilized during –X translation. This assures that no more than three forward tank jets are simultaneously commanded on nominally, reducing the likelihood of helium gas ingestion in the forward propellant tank lower compartment.

The high-level roll command (Figures 4.4.4.2.2.1–8 and –9) condition increases the number of roll jets used, when possible, if a yaw rotation is commanded simultaneously with roll in a direction that couples unfavorably into the roll axis. This is required to overcome very large roll coupling due to inertia properties with a connected ET.

The high yaw command logic (Figure 4.4.4.2.2.1–8A) increases the number of aft yaw jets used if the following conditions apply: (1) –Z translation is commanded, (2) both yaw jets and both +pitch jets on the same side of the nose have failed (e.g., two manifold closures), and (3) the commanded yaw opposes the failure-induced disturbance.

The purpose of the pitch/roll rate reduction logic (Figure 4.4.4.2.2.1–10) is to reduce the number of jets used for combined –pitch and roll maneuvers after ET separation. This results in a reduced likelihood of exceeding the number of simultaneous jet firings that cause helium gas ingestion into the RCS propellant tank lower compartment.

The failure reconfiguration block (Figure 4.4.4.2.2.1–11) outputs several discretes which indicate failure status of various jet groupings. It is executed only when JET_FAIL_CHANGE_FLAG is set ON. JET_SELECT_TRANSITION then resets this flag. The outputs are as follows:

1. HFAIL_JSL is the complement of AVAILABLE_JET_FWD and AVAILABLE_JET_AFT mapped into the array order used within the jet selection algorithms.
2. NEG_ZFAIL indicates failure status in the two aft –Z firing jet groups.
3. NO_DUMP indicates failure status in the nose Y jets.

The forward propellant dump logic (Figure 4.4.4.2.2.1–12) block executes only when the forward RCS dump is required and is possible. It determines whether two or four opposing Y jets in the nose are to fire and outputs the commands. It also reduces attitude control to aft only by turning off other forward jets. Translation is inactive when this option is in use.

Figure 4.4.4.2.2.1-13 shows RCS jet locations and plume directions.

4.4.4.2.2.2 PHASE_PLANE_TRANSITION.

A. Function. For each body axis requiring RCS rotation control and not in the manual rotation acceleration submode, this module determines whether an angular rate change is needed and the sign of the desired rate change. The sign and magnitude of the desired rate error and the RCS rotation commands are supplied to the OMS processor as well. The module operates individually by axis. The algorithm drives and holds the vehicle in a limit cycle about the desired attitude and attitude rate. Rate error extrapolation logic compensates for lags in RCS jet thrust buildup and angular rate measurement. The block diagrams for the module PHASE_PLANE_TRANSITION are presented in Figures 4.4.4.2.2.2-1 and 4.4.4.2.2.2-2. Region boundaries and control actions of the function P_P_TRANSITION are shown in Table 4.4.4.2.2.2-1. The switching lines are defined in Table 4.4.4.2.2.2-2.

B. Processing Rate. The module PHASE_PLANE_TRANSITION is processed at 12.5 Hz.

C. Interface Requirements. The interface requirements for the module PHASE_PLANE_TRANSITION are shown in Table 4.4.4.2.2.2-3.

D. K-Loads/Constants. The K-loads/constants for the module PHASE_PLANE_TRANSITION are shown in Table 4.4.4.2.2.2-4.

E. Initialization Requirements. Initialization requirements for the module PHASE_PLANE_TRANSITION are shown in Table 4.4.4.2.2.2-5.

Table 4.4.4.2.2.2-1. Control Actions by Function P_P_TRANSITION in Regions of the Phase Plane

Region	Action	Region Definition
1	ROT_JET_CMD = - SE; IF X2 ≤ S3 THEN k = MINIMUM [k + 1, KLIM]; and WED = - SE WLOW ELSE k UNCHANGED and WED = SE WHIGH	X1 ≥ S1 or X2 > S3

FIGURE 4.4.4.2.2.2-2. Phase Plane for Function P_P

4.4.4.2.3 OMS Processor.

4.4.4.2.3.1 TVC_LAW_PITCH_YAW.

A. Function. This module closes the inner loop of the TVC DAP. Commanded pitch and yaw rates and the corresponding desired rate errors are subtracted from the vehicle rates to form rate errors, which are processed by compensation filters and passed through proportional-plus-integral paths. The integral paths are incremented as a function of the RCS rotation commands. The outputs are limited and passed on as position commands to the OMS engine actuator servos. Initialization of this module consists of subfunctions, which are invoked as required. These subfunctions are described separately, and the initialization modes are then summarized.

The pitch and yaw channels each consist of an upstream error determination and filter section, and a downstream proportional-plus-integral path and limiting section (Figure 4.4.4.2.3.1-1). A switch between the sections, operated by the initialization flag, allows a trim mode, with the downstream section operating alone with input zeroed, and a dynamic mode, with the sections connected together.

The K-loaded trim angles can be over written by adjusting the values of OMS_PITCH_TRIM and OMS_YAW_TRIM via the maneuver display principal function; or the trim angles may be left alone, in which case they would either be their K-loaded values or the values remaining from the previous burn. Operating the downstream section causes the existing trim value to be output from the module as the engine pitch and yaw commands. In case of a mid-burn transition from two OMS engines to one engine, the trim angles are automatically adjusted for thrusting through the c.g. by the use of internally stored constants.

The OMS_PITCH_TRIM and OMS_YAW_TRIM values provided by the maneuver display principal function are identified in the principal function interface tables (See Tables 4.4.2-1, 4.4.2-2, and 4.4.5-1) using different MSID and Level B mnemonic numbers from those numbers used to identify the trim values which are outputs from this module. Providing unique identification for the input and output values is done for accounting of principal function interfaces only and is not intended to preclude the possibility of using a common compool location for storage of both values.

Dynamic gains must also be adjusted as a function of the number of OMS engines operating. Thus, on the first dynamic pass following prethrust trimming or upon a two to one engine transition, the reconfiguration module indicates the number of engines via a gain flag and forces a gain calculation via the initialization flag. The first dynamic pass also requires initialization of the filters. The various initialization modes are summarized below.

<u>Initialization Flag Value</u>	<u>Description</u>	<u>Action</u>
0	Normal dynamic pass	Operate both sections of module.
1	Prethrust trim	Zero filter nodes, set trim angles to externally supplied values, and operate downstream section only.
2	Two to one engine transition trim	Set trim angles to internal one engine values, calculate gains, and operate both sections of module.
3	First dynamic pass after prethrust trim	Calculate gains and operate both sections.

These modes are sequenced as follows:

<u>Event</u>	<u>Initialization Flag Value</u>
Prethrust trim commanded	1
Engine(s) ignition	3
Engine(s) on, subsequent	0
Midburn two to one engine transition	2
Remainder of burn	0

The detailed block diagram for TVC_LAW_PITCH_YAW is presented in Figure 4.4.4.2.3.1-1.

B. Processing Rate. TVC_LAW_PITCH_YAW is processed at 12.5 Hz.

C. Interface Requirements. The interface requirements for TVC_LAW_PITCH_YAW are shown in Table 4.4.4.2.3.1-1.

D. K-Loads/Constants. The K-loads/constants for TVC_LAW_PITCH_YAW are shown in Table 4.4.4.2.3.1-2.

E. Initialization Requirements. The initialization requirements for TVC_LAW_PITCH_YAW are shown in Table 4.4.4.2.3.1-3.

4.4.4.2.3.2 TVC_LAW_ROLL.

A. Function. This module provides control of the vehicle in roll during two-engine TVC burns. Commanded roll rate and desired rate error are subtracted from the vehicle rate to form a rate error, which is processed by a compensation filter and passed through proportional-plus-integral paths. The integral path is incremented as a function of the RCS rotation command and limited. The output is passed on as a roll command to the TVC mixer module. The detailed block diagram for TVC_LAW_ROLL is presented in Figure 4.4.4.2.3.2-1.

B. Processing Rate. TVC_LAW_ROLL is processed at 12.5 Hz.

C. Interface Requirements. The interface requirements for TVC_LAW_ROLL are shown in Table 4.4.4.2.3.2-1.

D. K-Loads/Constants. The K-loads/constants for TVC_LAW_ROLL are shown in Table 4.4.4.2.3.2-2.

E. Initialization Requirements. The initialization requirements for TVC_LAW_ROLL are shown in Table 4.4.4.2.3.2-3.

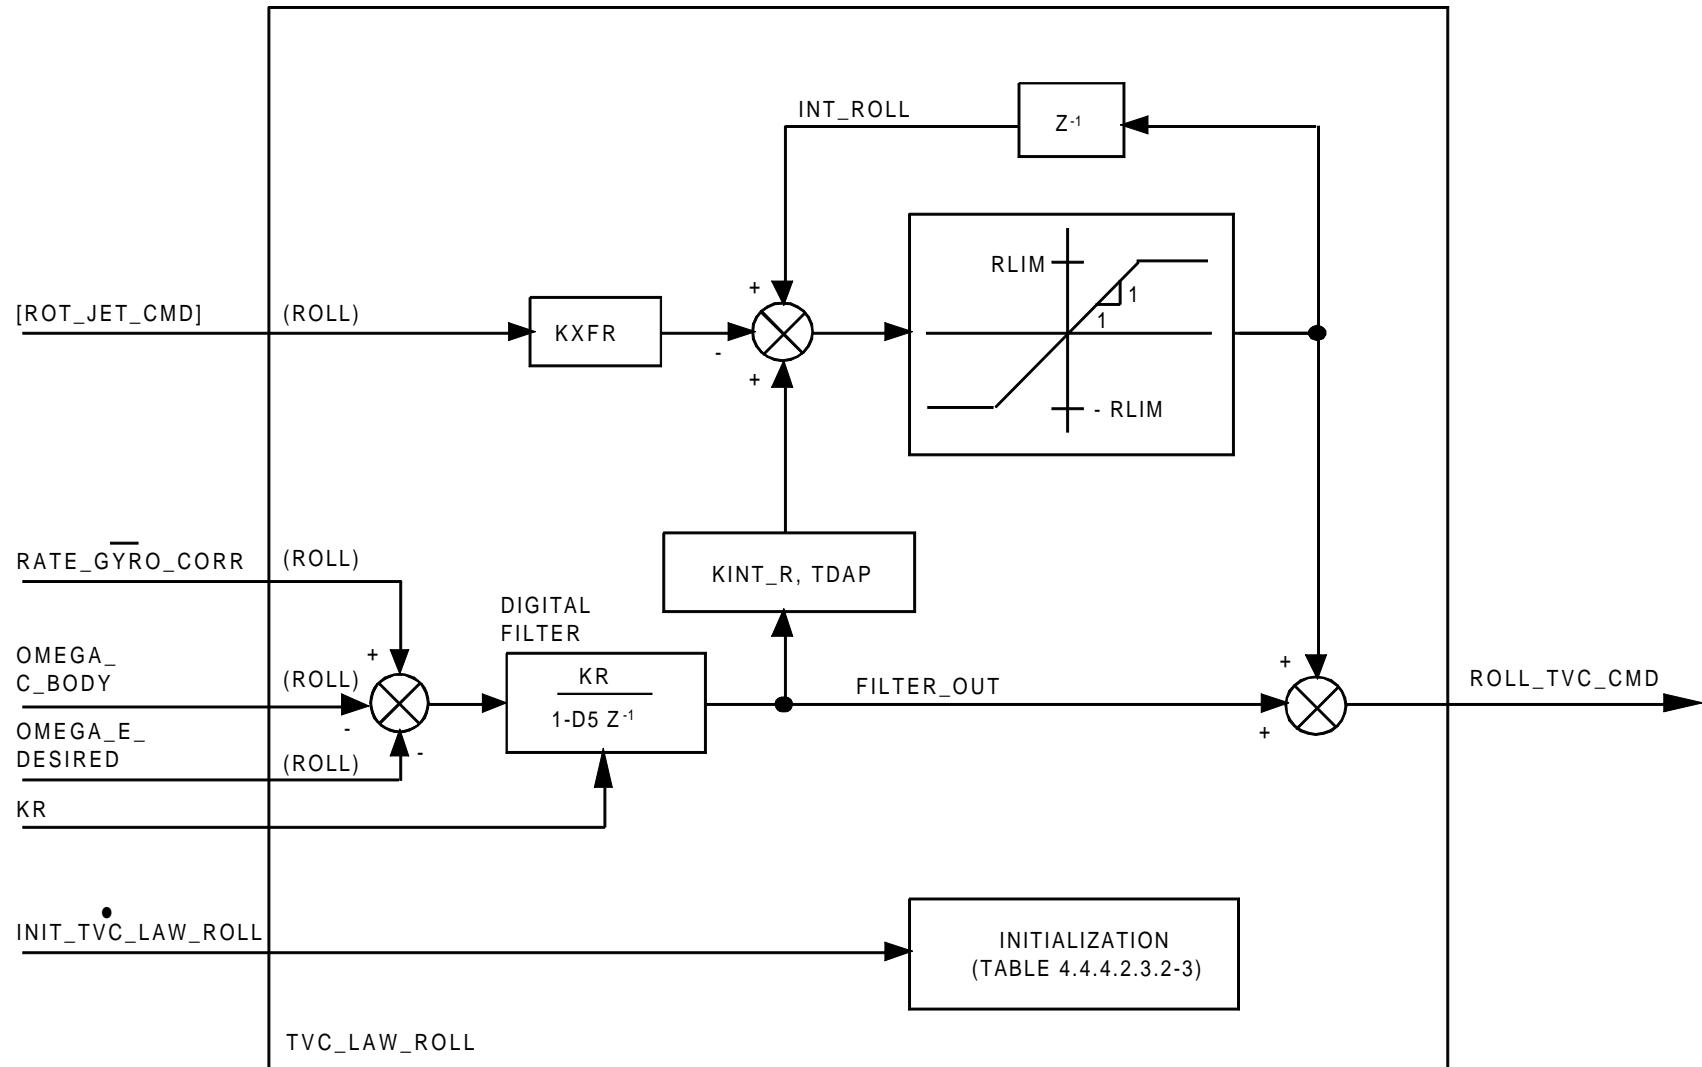

FIGURE 4.4.4.2.3.2-1. TVC_LAW_ROLL

4.4.4.2.3.3 TVC_MIXER.

A. Function. This module derives the left and right OMS pitch actuator servo commands as the difference and sum respectively of the pitch and roll TVC commands. The roll command is limited as a function of the pitch command, so that the total pitch command cannot exceed the desired limit. The detailed block diagram for the module TVC_MIXER is presented in Figure 4.4.4.2.3.3-1.

B. Processing Requirements. The module TVC_MIXER is processed at 12.5 Hz.

C. Interface Requirements. The interface requirements for the module TVC_MIXER are shown in Table 4.4.4.2.3.3-1.

D. K-Loads. The K-loads for the module TVC_MIXER are shown in Table 4.4.4.2.3.3-2.

E. Initialization Requirements. There are no initialization requirements for TVC_MIXER.

Table 4.4.4.2.3.3-1. TVC_MIXER Interface Requirements						
Name	Description	Source or Destination	Type	Range	Unit	Sample Rate (Hz)
Inputs						
OMSL_PITCH_YAW_CMD (pitch element)	Left OMS engine pitch and yaw servo commands	TVC_LAW_PITCH_YAW	A(2)S	Pitch: -5 to 5, Yaw: -8 to 8	deg	12.5
ROLL_TVC_CMD	Roll component of pitch servo command for OMS engines	TVC_LAW_ROLL	S	-20 to 20	deg	12.5
Outputs						
OMSL_PITCH_YAW_CMD (pitch element)	Left OMS engine pitch and yaw servo commands	OMS TVC CMD SOP	A(2)S	Pitch: -6 to 6, Yaw: -8 to 8	deg	12.5
OMSR_PITCH_YAW_CMD (pitch element)	Right OMS engine pitch and yaw servo commands	OMS TVC CMD SOP	A(2)S	Pitch: -6 to 6, Yaw: -8 to 8	deg	12.5

4.4.5 Transition DAP Principal Function Tables.

The transition DAP principal function IDD inputs and outputs are listed in Tables 4.4.5-1 and 4.4.5-2. Values for the I-loads are contained in the I-loads requirements document (JSC-19350); however, I-load definitions applicable to this principal function are listed in Table 4.4.5-3. K-loads are listed in Table 4.4.5-4.

The automated Interface Definition Document (IDD) table (Tables 4.4.5-1 and 4.4.5-2) defines signal (parameter) interface requirements either between hardware (LRU) and software elements or between software elements and other software elements.¹ In the event of a conflict between the IDD tables and other internal text input/output tables, the SASCB data base-controlled IDD tables take precedence.

¹ A GN&C software element is either a sequenced principal function, crew-generated specialist/display function, or an OPS display function.

Note that IDD output (source) tables which reflect parameters going to input (destination) “TLM” shall not be interpreted as a signal actually being downlisted. The parameter may only be available for downlist in COMPOOL and may not appear in a downlist format.

R.2 HISTORICAL CHANGE REQUEST SUMMARY

Table R.2-1. is an historical record of approved change requests incorporated since the initial baseline up to OI-25. Change requests commencing with OI-26 are reformatted and listed in the CR Reference Summary.

Table R.2-1. Historical Change Request Summary

CR No.	OI	CR Title
12071A		MNVR Executive
12088		RCS Downmoding Logic Correction
12090D		Deorbit DIP Trim Angles
12109		On-Orbit 1 I/O Update
12190D		PEG Mode TAEM Approved for Changes Ascent/RTLS Guidance
12225B		GN&C LVLV U/L Requirements
12233		Transition DAP Rate Change
12257		Lack of Error Needles, +X RCS Burn
12269		MSID Corrections
12270A		Block Update to OPS-3
12313C		Addition to TLM Requirements
12316		GN&C SW RM Rate Change
12317		A/E ATT PROC Rate, TRANS_DAP
12334		Deorbit DIP/TRANS DAP I/F Change
12336		I-Load for OFT-1 Baseline
12337		I-Load for OFT-1 Baseline
12356A		3-Axis Pulse Mode, TRANS_DAP
12369D		RCS RM
12411B		OMS FDI Simplification
12413C		TRANS_DAP Mod/Rate Gyro Noise
12443		I-Load for Entry FACI
12474C		Reduce IMU Velocity Processing Rate
12485B		TRANS_DAP Cleanup
12543A		Delete JSL Pre-ET Separation Roll/Yaw Coupling Logic
12565		TRANS_DAP Minimum Impulse
12586		Integrated Signal, Maneuver DIPS
12624A		S/W Mod Required to Support FCS SW Changes
12689B		Command Body Attitude During OMS Burn
12690		Definition of TVC P/Y Integrator Limits
12744		Vehicle Thrust Body Geometry
12781A		Vehicle OMS Trim Angle I/F

Table R.2-1. Historical Change Request Summary

CR No.	OI	CR Title
12833A		Jet Selection Change
12866B		Add Auto +X Capability to TRANS_DAP
12874		CR 12485 Cleanup
12948		Addition of Automatic Maneuver
12975		3-Axis RHC Detent
12981D		On-Orbit Flight Control
12993		I-Loads FACI
12994		I-Load FACI
19010		I-Load, MSID's for All New Parameters in 9-4-78/9-11-78 SCB Baseline of 9-21-78
19065		I-Load Discrepancy Cleanup
19100		FSSR Update
19143		ET Separation Documentation Change
19179		TRANS_DAP/RCS SOP Rate Reduction
19658		Jet Selection Modifications to Maintain Attitude Control During ET Separation With Two Failures
19712		Corrections to I-Load Data Tape for CPDS
19757A		Correction to TRANS DAP RHC
19777A		STS-2 Requirements Incorporation Into STS-1 Code, TRANS DAP
19827A		-Z Maneuver Initialization Modification
29000		JSL Changes to Assure Front Strut Clearance During ET Separation
29191		Actuation of RCS Jet Activity Lights During OPS 2, OPS 8, and MM 301-303
29300		FSSR Update No. 6
29341		Delete OMS Delta V Indicator
29407C		MNVR EXEC DISP PFS 18/BFS 12
29438		TRANS DAP Disc Rate Reduction
29466B		Simplified TRANS DAP Pulse Mode
29471B		HFE Overrun Definition
29497C		OMS Actuator Lock-Up Inhibit I/L
29500		FSSR Update No. 7
29509D		TRANS DAP Low Bandwidth TVC
29543A		RCS Firings During OMS/Shutdown
29565		High -Z Translation Change
29566A		Single-Axis Translation Logic
29567A		Combined -Pitch/Roll Acceleration
29568A		-X Translation Aft Pitch Default

Table R.2-1. Historical Change Request Summary

CR No.	OI	CR Title
29575A		TRANS DAP I/L to Constants
29667A		Eliminate TRANS DAP I-LOADS
29719		TRANS DAP/RCS RM Signal
29722		Pitch/Roll Rate Reduction
29762A		ATT_PROC IDD Cleanup
29787A		I-Load OMS/RCS Force Flight
29800		FSSR Updated
29879		TRANS DAP Rate and Attitude D/B I/L
29947		TRANS DAP Attitude Error Sign
39000		FSSR Update No. 9
39012		DAP TVC Filter Gain I-Loads
39014		Remove Duplicate DAP MSID's
39074A		OMS TVC Yaw Limit Changes
39155D		RCS Jet Priority Control
39250B		Flight Control for IUS P/L
39401A		Transatlantic Abort Landing
39407A		TRANS DAP AUTO MNVR Rate
39419		TRANS_DAP Constant Changes
39431A		ADI ERROR from Q_B_I_CMD
39445		ET SEP AUTO MNVR Initiate
39449		TRANS DAP AUTO MNVR Logic
39552		TVC_MIXER and TRANS DAP I/L
39849		ET_SEP Complete Flag in OPS 3
39856		Augmentation of CR 39449
39990E		STS-5 Cycle 3 ASC I-Loads
39997		Doc UPDATE-TRANS and Orbit DAP's
59187		TRANS DAP Parameter Renaming
59205		TRANS DAP AUTO MNVR Rate I/L (Ref Only)
59350		FSSR Update
59570		Clarify TRANS_RECON Pulse
59924A		Derived BFS IL's to Accommodate IMRB (Ref Only)
69070		FSSR Update
69220		Centaur Abort Dump
69700		FSSR Update
79044		FSSR 83-0008 Document Correction
79081		Document Correction of CR 39849
79166C		RCS Document Priority Corrections

Table R.2-1. Historical Change Request Summary

CR No.	OI	CR Title
79499		FSSR Update 5
79790A		CR Implementation Baseline—November 1985
79962F		Entry/GRTLS DAP OI-8C Scrub
89140E		CENTAUR Requirements Deletion
89150H		Abort Control Sequence Scrub
89181F		Errata STS 83-0008A Vol. 2
89245D		Post MECO TAL Declaration
89250B		Bailout Control System
89461A		FSSR STS 83-0002B 8B Errata B/L
89494A		FSSR10 Errata/Document Cleanup
89495B		FSSR STS 83-0008B V2 8B Errata
89558A		OI-8C FCS Scrub Cleanup
89599C		Cleanup Level B GN&C Document
89645A		FSSR STS 83-0008B V2 Errata Update
89662B		FSSR STS 83-0003B Errata Update
89688A		FSSR STS 83-0008B V1 8B Errata
89741B		Errata SS 830010B
89853B		1 OMS ENG to 2 OMS Reconfig
89903B		Add Fuel Dissipation
89921C	20	Close Loop PRCS Pulse Mode
90054A		Entry FCS Errata Ref to MM
90120B		Update Guidance Downmode Requirement
90185A	20	Add CR Field to FSSR I/O Tables
90221		Change TLAMC From MET to GMT
90353G	23	Transition Flight Control I-Load to K-Load Conversion
90374C	20	Automated FSSR Constants
90476D	25	Wraparound Yaw Jet System w/PTI Effector
90606D	22	PFS/ BFS ICD Baseline
90705H	25	3 Engines Out Auto Contingency
90790	24	Add Memory Configuration to the FSSR I-Load Tables
90814C	24	Add Description of Database Generated FSSR Paramter Tables
90964	25	Interface Clarification for 3 Engines Out—CR 90705H
90966A	24	Deletion of the Qualifier from the FSSR I-Load Tables
91066D	25	Standardize the FSSR Correlation Tables
92027B	25	TDMS-2 Required FSSR Changes
