NOTES:

## LM DOCKED ALIGNMENT

## Docking Tunnel Index Angle:

$R_c =$  \_\_\_\_\_ deg. (Recorded during 1st IVT to LM  
Verified during succeeding IVT's)

## Docked Coarse Align:

1. CSM should be in Min. Deadband, Attitude Hold.
2. CMP executes V06N20E and reports ICDU angles.
3. CDR calculates coarse align angles:

Outer Gimbal	Inner Gimbal	Middle Gimbal
300.00°	180.00°	360.00°
+ _____ $R_c$		
- _____ $X_{cm}$	+ _____ $Y_{cm}$	- _____ $Z_{cm}$
= _____ $X_{lm}$	= _____ $Y_{lm}$	= _____ $Z_{lm}$

4. CDR executes V41N20E and loads X, Y, Z CDU angles.
5. CDR executes V40N20E -- IMU goes inertial.

NOTE: The accuracy of this procedure is limited by  
(a) the coarse align accuracy of the ISS  
(b) vehicle attitude changes between steps 2 and 5.

## Docked Fine Align:

6. CMP and CDR enter simultaneous V06N20 in CM and LM. The ICDU angles are recorded and reported to MCC.

GET = \_\_\_\_\_:\_\_\_\_\_:\_\_\_\_\_ (for gyro drift calculation)

	Outer Gimbal	Inner Gimbal	Middle Gimbal
CM:	_____	_____	_____
LM:	_____	_____	_____

7. MCC calculates gyro torquing angles and reports them to LM.

LM GTA's = \_\_\_\_\_ X, \_\_\_\_\_ Y, \_\_\_\_\_ Z

8. CDR disables jet firings and performs fine align (V42E), loading the gyro torquing angles voiced up from MCC.

## LM GYRO DRIFT

## Docked (Noun 20 Method)

The LM IMU drift check is performed by MCC using a set of simultaneous CM and LM ICDU angles.

Crew Report: GET \_\_\_\_\_:\_\_\_\_\_:\_\_\_\_\_  $\Delta T =$  \_\_\_\_\_ hrs.  
(Time since previous Noun 20)

	Outer Gimbal	Inner Gimbal	Middle Gimbal
CM:	_____	_____	_____
LM:	_____	_____	_____

MCC calculates gyro torquing angles:  \_\_\_\_\_ X,  \_\_\_\_\_ Y,  \_\_\_\_\_ Z  
.230°X, .520°Y, 1.90°Z

The above limits are based on the following requirements:

1. Maximum platform misalignment at PDI = .19° about  $X_{sm}$  to assure that crossrange error at touchdown < 1 kilometer.
2. Maximum platform misalignment at PDI = .5° about  $Y_{sm}$  to assure a safe descent abort capability.
3. PNGCS is No/Go if drift rate > 100 meru about any axis.

Although the restrictive requirements concern the state of platform alignment at PDI, high drift rate can negate a perfect platform realignment (P52) performed 80 minutes before PDI.

The equivalent drift rates allowable are:

.145 deg/hr (X) .376 deg/hr (Y) 1.5 deg/hr (Z)

The GTA limits utilize these drift rates, assume 75 minutes between Noun 20 entries, and allow .05° for total measurement error.

## Undocked (P52 Method)

The gyro torquing angles obtained during the IMU realignment program (P52) can be used to calculate the rate of platform drift since the last realignment.

Rev. 12 P52 GET = \_\_\_\_\_:\_\_\_\_\_:\_\_\_\_\_

Time of previous align = \_\_\_\_\_:\_\_\_\_\_:\_\_\_\_\_

$\Delta T$  (difference) = \_\_\_\_\_:\_\_\_\_\_:\_\_\_\_\_ hours

Gyro Torquing Angles  \_\_\_\_\_°(X)  \_\_\_\_\_°(Y)  \_\_\_\_\_°(Z)

$\div (.015)\Delta T$  (S) S = -1 S = -1 S = +1

= Drift Rate (meru): \_\_\_\_\_(X) \_\_\_\_\_(Y) \_\_\_\_\_(Z)

NOTE: As presently planned, the Rev. 12 GTA's will be torqued out to serve as a baseline for the Rev 13 P52. The time-of-previous-align used in the Rev 12 drift calculation will nominally be the GET of the P52 GTA's during Docked Fine Align. However, allowance must be made for any changes in the compensation values during this period. In spite of the GTA limits defined for Docked Gyro Drift (above), Mission Rules provide for uplinking new compensation values whenever the drift rate exceeds 5 meru on any axis.

Rev. 13 P52 GET = \_\_\_\_\_:\_\_\_\_\_:\_\_\_\_\_

Time of Previous Align = \_\_\_\_\_:\_\_\_\_\_:\_\_\_\_\_

$\Delta T$  (difference) = \_\_\_\_\_:\_\_\_\_\_:\_\_\_\_\_ hours  
(2.0)

Gyro Torquing Angles  \_\_\_\_\_°(X)  \_\_\_\_\_°(Y)  \_\_\_\_\_°(Z)  
Limits .370° .830° 3.000°

GTA  $\div (.015)\Delta T$  (S) S = -1 S = -1 S = +1

= Drift Rate (meru): \_\_\_\_\_(X) \_\_\_\_\_(Y) \_\_\_\_\_(Z)

NOTE: The Rev 13 GTA's will be torqued if they do not exceed the limits shown. These limits are based on the equivalent drift rates allowed during the Docked Gyro Drift measurement (above). They assume 2.0 hours between the two P52's, and allow .08° for AGT measurement errors. If the limits are exceeded PDI will be delayed 1 Rev.

## BASIC REFERENCE COORDINATES AND REFSMMAT

The Basic Reference Coordinate system (BRC) is an orthogonal inertial coordinate system whose origin is located either at the earth or moon center of mass (Figure 1). The orientation of this coordinate system is defined by the line of intersection of the mean earth equatorial plane and the mean ecliptic at the beginning of the Besselian year which starts January 1, 2516251, 1972. The X axis ( $\underline{u}_{XP}$ ) is defined by the intersection of the earth's equatorial plane and the ecliptic in the direction of the ascending node. The Z axis ( $\underline{u}_{ZP}$ ) is along the mean earth north pole, and Y axis ( $\underline{u}_{YP}$ ) completes the right-handed triad.

This coordinate system is shifted from earth-centered to moon-centered when estimated vehicle position from the moon falls below 64,373,760 meters. It is likewise shifted from the moon back to the earth when the spacecraft position exceeds 64,373,760 meters. All navigation stars, lunar-solar ephemerides and vehicle state vectors are referenced to this system (Figure 2).

REFSMMAT. The matrix used to transform the elements of a vector given in BRC space to IMU space is known as REFSMMAT.

Nine REFSMMAT's or IMU alignments are utilized during this mission. Each is a unique matrix which locates a stable member axis ( $\underline{u}_{XSM}$ ,  $\underline{u}_{YSM}$ , or  $\underline{u}_{ZSM}$ ) in BRC space (Figure 3).

IMU REALIGNMENT. Any desired IMU orientation with respect to the BRC system and its associated REFSMMAT can be obtained from star sightings (Program P52).

The procedure generally used to change the alignment of the IMU from one of the five primary attitudes to another is as follows:

- The astronaut executes Program P52, Option 3. This realigns the IMU to the present inertial attitude thereby eliminating the effects of gyro drift.
- The astronaut executes Program P52, Option 1. The REFSMMAT for Option 1 is generally uplinked prior to entering P52. When executed, the program computes and displays the IMU gimbal angles for the desired IMU attitude using the present vehicle attitude.

A total of four options are available to the crew when executing P52 (Figure 4). The basic difference between options is the manner in which REFSMMAT is obtained. The basic orthogonalization procedure used to compute REFSMMAT is shown in Figure 5.
